Alternative Elliptic Curve Representations
draft-ietf-lwig-curve-representations-14

Abstract

This document specifies how to represent Montgomery curves and (twisted) Edwards curves as curves in short-Weierstrass form and illustrates how this can be used to carry out elliptic curve computations using existing implementations of, e.g., ECDSA and ECDH using NIST prime curves. We also provide extensive background material that may be useful for implementers of elliptic curve cryptography.

Requirements Language

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in BCP 14 [RFC2119] [RFC8174] when, and only when, they appear in all capitals, as shown here.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <https://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on May 19, 2021.

1. Fostering Code Reuse with New Elliptic Curves

Elliptic curves can be represented using different curve models. Recently, IETF standardized elliptic curves that are claimed to have better performance and improved robustness against "real world" attacks than curves represented in the traditional short-Weierstrass curve model. These so-called CFRG curves [RFC7748] use the Montgomery curve model and the model of twisted Edwards curves.

In this document, we specify these curves using the traditional short-Weierstrass model and also define how to efficiently switch between representations in these different curve models. In particular, we specify Wei25519, which allows an alternative representation of points of Curve25519 (a Montgomery curve) and of points of Edwards25519 (a twisted Edwards curve), as points of a corresponding short-Weierstrass curve. Similarly, we specify Wei448, which allows an alternative representation of points of Curve448 (a Montgomery curve) and of points of Ed448 (an Edwards curve), as points of a corresponding short-Weierstrass curve.

Use of Wei25519 and Wei448 allows easy definition of new instantiations of signature schemes and key agreement schemes already specified for traditional NIST prime curves, thereby allowing easy integration with existing specifications, such as NIST SP 800-56a [SP-800-56a], FIPS Pub 186-4 [FIPS-186-4], and ANSI X9.62-2005 [ANSI-X9.62], and fostering code reuse on platforms that already implement some of these schemes using elliptic curve arithmetic for curves in short-Weierstrass form (see Appendix C.1). To illustrate this, we specify how to use Wei25519 and Wei448 with co-factor ECDH and with ECDSA, thereby giving rise to the key agreement schemes ECDH25519 and ECDH448 and the signature schemes ECDSA25519 and ECDSA448. In all these cases, implementors may use the curve arithmetic for the curve model of their choosing (where they can efficiently switch between representations in different curve models, if required).

For ease of exposition, we consider Wei25519 first and introduce Wei448 simply as an illustration of how to create other "offspring" objects and protocols (see Section 4.4). We also provide extensive background material that we hope may be useful for implementors of elliptic curve cryptography or for cross-referencing with future specification work.

2. Specification of Wei25519

For the specification of Wei25519 and its relationship to Curve25519 and Edwards25519, see Appendix E. For further details and background information on elliptic curves, we refer to the other appendices.

The use of Wei25519 allows reuse of existing generic code that implements short-Weierstrass curves, such as the NIST curve P-256, to also implement the CFRG curves Curve25519 and Edwards25519. (Here, generic code refers to an implementation that does not depend on hardcoded domain parameters (see also Section 6).) We also cater to reusing of existing code where some domain parameters may have been hardcoded, thereby widening the scope of applicability. To this end, we specify the short-Weierstrass curves Wei25519.2 and Wei25519.-3, with hardcoded domain parameter $a=2$ and $a=-3 \pmod{p}$, respectively; see Appendix G. (Here, p is the characteristic of the field over which these curves are defined.)

3. Use of Representation Switches

The curves Curve25519, Edwards25519, and Wei25519, as specified in Appendix E.3, are all isomorphic, with the transformations of Appendix E.2. These transformations map the specified base point of each of these curves to the specified base point of each of the other curves. Consequently, a public-private key pair $(k,R:=k*G)$ for any

one of these curves corresponds, via these isomorphic mappings, to the public-private key pair $(k, R' := k * G')$ for each of these other curves (where G and G' are the corresponding base points of these curves). This observation extends to the case where one also considers curve Wei25519.2 (which has hardcoded domain parameter $a=2$), as specified in Appendix G.3, since it is isomorphic to Wei25519, with the transformation of Appendix G.2, and, thereby, also isomorphic to Curve25519 and Edwards25519.

The curve Wei25519.-3 (which has hardcoded domain parameter $a=-3 \pmod{p}$) is not isomorphic to the curve Wei25519, but is related in a slightly weaker sense: the curve Wei25519 is isogenous to the curve Wei25519.-3, where the mapping of Appendix G.2 is an isogeny of degree $l=47$ that maps the specified base point G of Wei25519 to the specified base point G' of Wei25519.-3 and where the so-called dual isogeny (which maps Wei25519.-3 to Wei25519) has the same degree $l=47$, but does not map G' to G , but to a fixed multiple hereof, where this multiple is $l=47$. Consequently, a public-private key pair $(k, R := k * G)$ for Wei25519 corresponds to the public-private key pair $(k, R' := k * G')$ for Wei25519.-3 (via the l -isogeny), whereas the public-private key pair $(k, R' := k * G')$ corresponds to the public-private key pair $(l * k, l * R = l * k * G)$ of Wei25519 (via the dual isogeny). (Note the extra scalar $l=47$ here.)

Alternative curve representations can, therefore, be used in any cryptographic scheme that involves computations on public-private key pairs, where implementations may carry out computations on the corresponding object for the isomorphic or isogenous curve and convert the results back to the original curve (where, in case this involves an l -isogeny, one has to take into account the factor l). This includes use with elliptic-curve based signature schemes and key agreement and key transport schemes.

For some examples of curve computations on each of the curves specified in Appendix E.3 and Appendix G.3, see Appendix J.

4. Examples

4.1. Implementation of X25519

RFC 7748 [RFC7748] specifies the use of X25519, a co-factor Diffie-Hellman key agreement scheme, with instantiation by the Montgomery curve Curve25519. This key agreement scheme was already specified in Section 6.1.2.2 of NIST SP 800-56a [SP-800-56a] for elliptic curves in short Weierstrass form. Hence, one can implement X25519 using existing NIST routines by (1) representing a point of the Montgomery curve Curve25519 as a point of the Weierstrass curve Wei25519; (2) instantiating the co-factor Diffie-Hellman key agreement scheme of

the NIST specification with the resulting point and Wei25519 domain parameters; (3) representing the key resulting from this scheme (which is a point of the curve Wei25519 in Weierstrass form) as a point of the Montgomery curve Curve25519. The representation change can be implemented via a simple wrapper and involves a single modular addition (see Appendix E.2). Using this method has the additional advantage that one can reuse the public-private key pair routines, domain parameter validation, and other checks that are already part of the NIST specifications. A NIST-compliant version of co-factor Diffie-Hellman key agreement (denoted by ECDH25519) results if one keeps inputs (key contributions) and outputs (shared key) in the short-Weierstrass format (and, hence, does not perform Steps (1) and (3) above).

NOTE: At this point, it is unclear whether this implies that a FIPS-accredited module implementing co-factor Diffie-Hellman for, e.g., P-256 would also extend this accreditation to X25519.

4.2. Implementation of Ed25519

RFC 8032 [RFC8032] specifies Ed25519, a "full" Schnorr signature scheme, with instantiation by the twisted Edwards curve Edwards25519. One can implement the computation of the ephemeral key pair for Ed25519 using an existing Montgomery curve implementation by (1) generating a public-private key pair $(k, R' := k * G')$ for Curve25519; (2) representing this public-private key as the pair $(k, R := k * G)$ for Ed25519. As before, the representation change can be implemented via a simple wrapper. Note that the Montgomery ladder specified in Section 5 of RFC7748 [RFC7748] does not provide sufficient information to reconstruct $R' := (u, v)$ (since it does not compute the v -coordinate of R'). However, this deficiency can be remedied by using a slightly modified version of the Montgomery ladder that includes reconstruction of the v -coordinate of $R' := k * G'$ at the end of the Montgomery ladder (which uses the v -coordinate of the base point of Curve25519 as well). For details, see Appendix C.1.

4.3. Specification of ECDSA25519

FIPS Pub 186-4 [FIPS-186-4] specifies the signature scheme ECDSA and can be instantiated not just with the NIST prime curves, but also with other Weierstrass curves (that satisfy additional cryptographic criteria). In particular, one can instantiate this scheme with the Weierstrass curve Wei25519 and the hash function SHA-256 [FIPS-180-4], where an implementation may generate an ephemeral public-private key pair for Wei25519 by (1) internally carrying out these computations on the Montgomery curve Curve25519, the twisted Edwards curve Edwards25519, or even the Weierstrass curve Wei25519.-3 (with hardcoded $a = -3$ domain parameter); (2) representing the result

as a key pair for the curve Wei25519. Note that, in either case, one can implement these schemes with the same representation conventions as used with existing NIST specifications, including bit/byte-ordering, compression functions, and the like. This allows generic implementations of ECDSA with the hash function SHA-256 and with the NIST curve P-256 or with the curve Wei25519 specified in this specification to reuse the same implementation (instantiated with, respectively, the NIST P-256 elliptic curve domain parameters or with the domain parameters of curve Wei25519 specified in Appendix E). We denote by ECDSA25519 the instantiation of ECDSA with SHA-256 and with curve Wei25519, where the signature (r,s) is represented as the right-concatenation of the integers r and s , each represented as fixed-size strings with tight MSB/msb ordering (see Appendix I).

4.4. Other Uses (Wei448, ECDH448, ECDSA448, and Others)

Any existing specification of cryptographic schemes using elliptic curves in Weierstrass form and that allows introduction of a new elliptic curve (here: Wei25519) is amenable to similar constructs, thus spawning "offspring" protocols, simply by instantiating these using the new curve in short-Weierstrass form, thereby allowing code and/or specifications reuse and, for implementations that so desire, carrying out curve computations "under the hood" on Montgomery curve and twisted Edwards curve cousins hereof (where these exist). This would simply require definition of a new object identifier for any such envisioned "offspring" protocol. This could significantly simplify standardization of schemes and help keeping at bay the resource and maintenance cost of implementations supporting algorithm agility [RFC7696].

We illustrate the construction of such offspring protocols for Curve448, another Montgomery curve recently standardized by IETF (see [RFC7748]). Similar to the case with Curve25519, one can represent points of this curve via different curve models, viz. as points of an Edwards curve (Ed448) or as points of a short-Weierstrass curve (Wei448). For the specification of Wei448 and its relationship to Curve448 and Ed448, see Appendix M. As with ECDH25519, one can now easily define a NIST-compliant version of co-factor Diffie-Hellman key agreement (denoted by ECDH448), by simply reusing the example of Section 4.1, but now using the short-Weierstrass curve Wei448, rather than Wei25519. Similarly, one can easily specify ECDSA with Wei448 and a suitable hash function, by simply reusing the example of Section 4.3, but now using the short-Weierstrass curve Wei448, rather than Wei25519, and picking as hash function SHAKE256 [FIPS-202] with output size of $d=512$ bits. We denote by ECDSA448 the resulting signature scheme (with the same bit/byte-ordering conventions).

5. Caveats

The examples above illustrate how specifying the Weierstrass curve Wei25519 (or any curve in short-Weierstrass format, for that matter) may facilitate reuse of existing code and may simplify standards development. However, the following caveats apply:

5.1. Wire Format

The transformations between alternative curve representations can be implemented at negligible relative incremental cost if the curve points are represented as affine points. If a point is represented in compressed format, conversion usually requires a costly point decompression step. This is the case in [RFC7748], where the inputs to the co-factor Diffie-Hellman scheme X25519, as well as its output, are represented in u-coordinate-only format. This is also the case in [RFC8032], where the EdDSA signature includes the ephemeral signing key represented in compressed format (see Appendix H for details). Note that in the latter case compression is lossless, whereas it is lossy in the former case.

5.2. Representation Conventions

While elliptic curve computations are carried-out in a field $GF(q)$ and, thereby, involve large integer arithmetic, these integers are represented as bit- and byte-strings. Here, [RFC8032] uses least-significant-byte (LSB)/least-significant-bit (lsb) conventions, whereas [RFC7748] uses LSB/most-significant-bit (msb) conventions, and where most other cryptographic specifications, including NIST SP800-56a [SP-800-56a], FIPS Pub 186-4 [FIPS-186-4], and ANSI X9.62-2005 [ANSI-X9.62] use most-significant-byte (MSB)/msb conventions. Since each pair of conventions is different (see Appendix I for details and Appendix J for examples), this does necessitate bit/byte representation conversions.

5.3. Domain Parameters

All traditional NIST curves are Weierstrass curves with domain parameter $a=-3$, while all Brainpool curves [RFC5639] are isomorphic to a Weierstrass curve of this form. Thus, one can expect there to be existing Weierstrass implementations with a hardcoded $a=-3$ domain parameter ("Jacobian-friendly"). For those implementations, including the curve Wei25519 as a potential vehicle for offering support for the CFRG curves Curve25519 and Edwards25519 is not possible, since it is not of the required form. Instead, one has to implement Wei25519.-3 and include code that implements the isogeny and dual isogeny from and to Wei25519. The lowest odd-degree isogeny has degree $l=47$ and requires roughly 9kB of storage for isogeny and

dual-isogeny computations (see the tables in Appendix G.4). Note that storage would have reduced to a single 64-byte table if only the Curve25519 curve would have been generated so as to be isomorphic to a Weierstrass curve with hardcoded $a=-3$ parameter (this corresponds to $l=1$).

NOTE 1: An example of a Montgomery curve defined over the same field as Curve25519 that is isomorphic to a Weierstrass curve with hardcoded $a=-3$ parameter is the Montgomery curve $M_{\{A,B\}}$ with $B=1$ and $A=-1410290$ (or, if one wants the base point to still have u -coordinate $u=9$, with $B=1$ and $A=-3960846$). In either case, the resulting curve has the same cryptographic properties as Curve25519 and the same performance (which relies on A being a 3-byte integer, as is the case with the domain parameter $A=486662$ of Curve25519, and using the same special prime $p=2^{255}-19$), while at the same time being "Jacobian-friendly" by design.

NOTE 2: While an implementation of Curve25519 via an isogenous Weierstrass curve with domain parameter $a=-3$ requires a relatively large table (of size roughly 9kB), for the quadratic twist of Curve25519 (i.e., the Montgomery curve $M_{\{A,B'\}}$ with $A=486662$ and $B'=2$) this implementation approach only requires a table of size less than 0.5kB (over 20x smaller), solely due to the fact that it is l -isogenous to a Weierstrass curve with $a=-3$ parameter with relatively small parameter $l=2$ (compared to $l=47$, as is the case with Curve25519 itself).

6. Implementation Considerations

The efficiency of elliptic curve arithmetic is primarily determined by the efficiency of its group operations (see Appendix C). Numerous optimized formulae exist, such as the use of so-called Montgomery ladders with Montgomery curves [Mont-Ladder] or with Weierstrass curves [Wei-Ladder], the use of hardcoded $a=-3$ domain parameter for Weierstrass curves [ECC-Isogeny], and the use of hardcoded $a=-1$ domain parameters for twisted Edwards curves [tEd-Formulas]. These all target reduction of the number of finite field operations (primarily, finite field multiplications and squarings). Other optimizations target more efficient modular reductions underlying these finite field operations, by specifying curves defined over a field $GF(q)$, where the field size q has a special form or a specific bit-length (typically, close to a multiple of a machine word). Depending on the implementation strategy, the bit-length of q may also facilitate reduced so-called "carry-effects" of integer arithmetic.

Most curves use a combination of these design philosophies. All NIST curves [FIPS-186-4] and Brainpool curves [RFC5639] are Weierstrass

curves with $a=-3$ domain parameter, thus facilitating more efficient elliptic curve group operations (via so-called Jacobian coordinates). The NIST curves and the Montgomery curve Curve25519 are defined over prime fields, where the prime number has a special form, whereas the Brainpool curves - by design - use a generic prime number. None of the NIST prime curves, nor the Brainpool curves, can be expressed as Montgomery or twisted Edwards curves, whereas - conversely - Montgomery curves and twisted curves can be expressed as Weierstrass curves.

While use of Wei25519 allows reuse of existing generic code that implements short Weierstrass curves, such as the NIST curve P-256, to also implement the CFRG curves Curve25519 or Edwards25519, this obviously does not result in an implementation of these CFRG curves that exploits the specific structure of the underlying field or other specific domain parameters (since generic). Reuse of generic code, therefore, may result in a less computationally efficient curve implementation than would have been possible if the implementation had specifically targeted Curve25519 or Edwards25519 alone (with the overall cost differential estimated to be somewhere in the interval [1.00-1.25]). If existing generic code offers hardware support, however, the overall speed may still be larger, since less efficient formulae for curve arithmetic using Wei25519 curves compared to a direct implementation of Curve25519 or Edwards25519 arithmetic may be more than compensated for by faster implementations of the finite field arithmetic itself.

Overall, one should consider not just code reuse and computational efficiency, but also development and maintenance cost, and, e.g, the cost of providing effective implementation attack countermeasures (see also Section 8).

7. Implementation Status

[Note to the RFC Editor] Please remove this entire section before publication, as well as the reference to [RFC7942].

This section records the status of known implementations of the protocol defined by this specification at the time of posting of this Internet-Draft, and is based on a proposal described in [RFC7942]. The description of implementations in this section is intended to assist the IETF in its decision processes in progressing drafts to RFCs. Please note that the listing of any individual implementation here does not imply endorsement by the IETF. Furthermore, no effort has been spent to verify the information presented here that was supplied by IETF contributors. This is not intended as, and must not be construed to be, a catalog of available implementations or their

features. Readers are advised to note that other implementations may exist.

According to [RFC7942], "this will allow reviewers and working groups to assign due consideration to documents that have the benefit of running code, which may serve as evidence of valuable experimentation and feedback that have made the implemented protocols more mature. It is up to the individual working groups to use this information as they see fit.

Nikolas Rosener evaluated the performance of switching between different curve models in his Master's thesis [Rosener]. For an implementation of Wei25519, see <<https://github.com/ncme/c25519>>. For support of this curve in tinydtls, see <<https://github.com/ncme/tinydtls>>.

According to <<https://community.nxp.com/docs/DOC-330199>>, an implementation of Wei25519 on the Kinets LTC ECC HW platform improves the performance by over a factor ten compared to a stand-alone implementation of Curve25519 without hardware support.

The signature scheme ECDSA25519 (see Section 4.3) is supported in <<https://datatracker.ietf.org/doc/draft-ietf-6lo-ap-nd/>>.

8. Security Considerations

The different representations of elliptic curve points discussed in this document are all obtained using a publicly known transformation, which is either an isomorphism or a low-degree isogeny. It is well-known that an isomorphism maps elliptic curve points to equivalent mathematical objects and that the complexity of cryptographic problems (such as the discrete logarithm problem) of curves related via a low-degree isogeny are tightly related. Thus, the use of these techniques does not negatively impact cryptographic security of elliptic curve operations.

As to implementation security, reusing existing high-quality code or generic implementations that have been carefully designed to withstand implementation attacks for one curve model may allow a more economical way of development and maintenance than providing this same functionality for each curve model separately (if multiple curve models need to be supported) and, otherwise, may allow a more gradual migration path, where one may initially use existing and accredited chipsets that cater to the pre-dominant curve model used in practice for over 15 years.

Elliptic curves are generally used as objects in a broader cryptographic scheme that may include processing steps that depend on

the representation conventions used (such as with, e.g., key derivation following key establishment). These schemes should (obviously) unambiguously specify fixed representations of each input and output (e.g., representing each elliptic curve point always in short-Weierstrass form and in uncompressed tight MSB/msb format).

To prevent cross-protocol attacks, private keys SHOULD only be used with one cryptographic scheme. Private keys MUST NOT be reused between Ed25519 (as specified in [RFC8032]) and ECDSA25519 (as specified in Section 4.3). Similarly, private keys MUST NOT be reused between Ed448 (as specified in [RFC8032]) and ECDSA448 (as specified in Section 4.4).

To prevent intra-protocol cross-instantiation attacks, ephemeral private keys MUST NOT be reused between instantiations of ECDSA25519 or ECDSA448.

9. Privacy Considerations

The transformations between different curve models described in this document are publicly known and, therefore, do not affect privacy provisions.

Use of a public key in any protocol for which successful execution evidences knowledge of the corresponding private key implicitly indicates the entity holding this private key. Reuse of this public key with more than one protocol or more than one protocol instantiation may, therefore, allow traceability of this entity. It may also allow correlation of meta-data communicated with this common data element (e.g., different addressing information), even if an observer cannot technically verify the binding of this meta-data.

The randomized representation described in Appendix K.5 allows random curve points to be represented as random pairs of field elements, thereby assisting in obfuscating the presence of these curve points in some applications.

10. Using Wei25519 and Wei448 with COSE and JOSE

This section defines algorithm encodings and representations enabling the use of the curves Wei25519 and Wei448 and their use with ECDH and ECDSA with JOSE [RFC7518] and COSE [RFC8152] messages.

All octet string encodings below use the MSB/msb-ordering conventions as defined in Appendix I.7. For CBOR representation details, we refer to [RFC7049]; for base64url encodings, we refer to [RFC4648].

10.1. Using Wei25519 and Wei448 Keys with COSE and JOSE

For Weierstrass curves, the representation of the point at infinity O is curve-specific (see Appendix H.1). For the short-Weierstrass curve Wei25519, we define $O:=(-1,0)$, whereas for Wei448, we define $O:=(1,0)$.

The encodings below specify the use of short-Weierstrass curves with COSE (see Section 10.1.1) and JOSE (see Section 10.1.2), where the encoding for a specific curve results by setting the "crv" parameter to the unique name of the curve in question (e.g., "Wei25519" for the curve Wei25519 and "Wei448" for the curve Wei448).

10.1.1. Encoding of Short-Weierstrass Curves with COSE

With COSE, points of short-Weierstrass curves are encoded using the "EC2" key type (Section 13.1.1 of [RFC8152]) or the "OKP" key type (Section 7.2 of [I-D.ietf-cose-rfc8152bis-algs]), which are instantiated by setting the "crv" parameter to the (unique) name of the curve in question and the "kty" parameter to "EC2" or "OKP", respectively, where key type-specific settings are as follows:

- a. With the "EC2" type, each affine point (X, Y) is encoded by setting the parameters "x" and "y" to the octet string representations of the elements X and Y , respectively, in tight MSB/msb-order, and converting each to a CBOR byte string. Each compressed point (X, t) is encoded by setting the parameter "x" to the octet representation of the element X , in tight MSB/msb-order, converted to a CBOR byte string, and by setting the parameter "y" to the CBOR False or CBOR True value, depending on whether, respectively, $t=0$ or $t=1$. For representation details and for details on the reverse mappings, see Appendix I.8. (Note that for affine points this representation is consistent with the "EC2" representation in Section 13.1.1 of [RFC8152].)
- b. With the "OKP" type, each point is encoded by setting the parameter "x" to the "squeezed" point representation of this point, in MSB/msb-order, and converting this to a CBOR byte string. For representation details and for details on the reverse mappings, see Appendix I.8. (Note that for affine points this representation is consistent with the "OKP" representation in Section 7.2 of [I-D.ietf-cose-rfc8152bis-algs], which affords a curve-specific octet string encoding.)

In either case, if the point is a public key, the parameter "d" encodes the corresponding private key, using the octet string representation, in tight MSB/msb-order, and converting this to a CBOR byte string (see Appendix I.6).

For curve points, the "crv" parameter and the parameters referenced with the applicable key type-specific settings above MUST be present in the structure, whereas the parameter "d" MUST NOT be present, while for private keys, the parameters "crv" and "d" MUST be present and the applicable key type-specific parameters of the corresponding public-key are RECOMMENDED to be present.

10.1.2. Encoding of Short-Weierstrass Curves with JOSE

With JOSE, points of short-Weierstrass curves are encoded using the "EC" key type (Section 6.2 of [RFC7518]) or the "OKP" key type (Section 2 of [RFC8037]), which are instantiated by setting the "crv" parameter to the (unique) name of the curve in question and the "kty" parameter to "EC" or "OKP", respectively, where key type-specific settings are as follows:

- a. With the "EC" type, each affine curve point (X, Y) is encoded by setting the parameters "x" and "y" to the octet string representations of the elements X and Y , respectively, in tight MSB/msb-order, and converting each using the base64url encoding. The point at infinity O is encoded as if this were an affine point. For representation details and details on the reverse mappings, see Appendix I.8. (Note that for affine points this representation is consistent with the "EC" representation in Section 6.2 of [RFC7518].)
- b. With the "OKP" type, each curve point is encoded by setting the parameter "x" to the "squeezed" point representation of this point, in MSB/msb-order, and converting this using the base64url encoding. For representation details and for details on the reverse mappings, see Appendix I.8. (Note that for affine points this representation is consistent with the "OKP" representation in Section 2 of [RFC8037], which affords a curve-specific octet string encoding.)

In either case, if the point is a public key (i.e., the private key is well-defined), the parameter "d" encodes the corresponding private key, using the octet string representation, in tight MSB/msb-order, and converting this using the base64url encoding (see Appendix I.6).

For curve points, the "crv" parameter and the parameters referenced with the applicable key type-specific settings above MUST be present in the structure, whereas the parameter "d" MUST NOT be present, while for private keys, the parameters "crv" and "d" MUST be present and the applicable key type-specific parameters of the corresponding public-key are RECOMMENDED to be present.

10.2. Using ECDSA25519 and ECDSA448 with COSE and JOSE

FIPS Pub 186-4 [FIPS-186-4] specifies the signature scheme ECDSA and can be instantiated with suitable combinations of elliptic curves in short-Weierstrass form and hash functions (that satisfy particular cryptographic criteria). While this completely specifies the internal workings of the signing and signature verification operations, this does not uniquely specify the input/output formats:

- a. The signing operation takes as inputs a message m (represented as a bit string) and a private key d in the interval $[1, n-1]$ and produces as output a signature, which is an ordered pair (r, s) of integers in the interval $[1, n-1]$, where n is the order of the base point of the curve in question;
- b. The signature verification operation takes as inputs a message m , a public key Q , and a signature (r, s) and produces as output the value "valid" or "invalid", depending upon whether the message was purportedly signed by a holder of the private key of the public-private key pair (d, Q) for the curve used with the signature scheme in question.

All inputs and outputs are uniquely determined by specifying the encodings of the message m , the private key d , the public key Q , the signature, and the values "valid" and "invalid".

The encodings below specify the use of instantiations of ECDSA with COSE (see Section 10.2.1) and JOSE (see Section 10.2.2), where the encoding for a specific ECDSA instantiation (i.e., with a specific short-Weierstrass curve and specific hash function) results by setting the "crv" parameter to the unique name of the underlying curve in question and the "alg" parameter to the unique name of the specific signature scheme instantiation (e.g., "ECDSA25519" for the ECDSA scheme defined in Section 4.3 and "ECDSA448" for the scheme defined in Section 4.4). Note that, in this case, the "alg" name uniquely defines the curve (and, thereby, implicitly the underlying "crv" parameter) and the underlying hash function.

10.2.1. Encoding of ECDSA Instantiations with COSE

Instantiations of ECDSA used with COSE use the following encodings of inputs and outputs:

- a. The message m is the COSE_Sign structure as specified in Section 4.1 of [RFC8152], converted to a bit-string, using the OS2BS mapping of Appendix I.4;

- b. The public key Q and the private key d are encoded as specified in Section 10.1.1, where the "crv" parameter is set to the unique name of the curve used with this particular instantiation of ECDSA;
- c. The Cose signature is encoded as the right-concatenation of the octet string representations of the coordinates of the signature pair (r, s) , in left-to-right order, where r and s are each represented as octet strings in tight MSB/msb-order using the ZnE2OS mapping of Appendix I.6, converted to a CBOR byte string. Note that, since we use a tight representation, this right-concatenated octet string has fixed size $2 \cdot l$, where the parameter l is uniquely defined by the set Z_n in question. The inverse mapping results by checking that the purported encoded signature (after CBOR decoding) has indeed size $2 \cdot l$, and by converting the left-side and right-side halves of this octet string (each of length l) to, respectively, the integers r and s in Z_n , via the strict OS2ZnE mapping of Appendix I.6.

When using a COSE key for this algorithm, if the "alg" field is present, it MUST be set to the (unique) name of this particular instantiation of ECDSA and the "crv" parameter MUST be set to the (unique) name of the corresponding curve; if the "key_ops" field is present, it MUST include "sign" when creating an ECDSA signature and it MUST include "verify" when verifying an ECDSA signature.

10.2.2. Encoding of ECDSA Instantiations with JOSE

Instantiations of ECDSA used with JOSE use the following encodings of inputs and outputs:

- a. The message m is the JWS Signing Input as specified in [RFC7515], converted to a bit-string, using the OS2BS mapping of Appendix I.4;
- b. The public key and the private key are encoded as specified in Section 10.1.2, where the "crv" parameter is set to the unique name of the curve used with this particular instantiation of ECDSA;
- c. The JWS signature is encoded as the right-concatenation of the octet string representations of the coordinates of the signature pair (r, s) , in left-to-right order, where r and s are each represented in tight MSB/msb-order (see Appendix I.7), converted using the base64url encoding. Note that, since we use a tight representation, this right-concatenated octet string has fixed size $2 \cdot l$, where the parameter l is uniquely defined by the set Z_n in question. The inverse mapping results by checking that

the purported encoded signature (after base64url decoding) has indeed size $2 \cdot l$, and by converting the left-side and right-side halves of this octet string (each of length l) to, respectively, the integers r and s in Z_n , via the strict OS2ZnE mapping of Appendix I.6.

When using a JOSE key for this algorithm, if the "alg" field is present, it MUST be set to the (unique) name of this particular instantiation of ECDSA and the "crv" parameter MUST be set to the (unique) name of the corresponding curve; if the "key_ops" field is present, it MUST include "sign" when creating an ECDSA signature and it MUST include "verify" when verifying an ECDSA signature; if the JWK _use_ field is present, its value MUST be "sig".

10.3. Using ECDH25519 and ECDH448 with COSE and JOSE

NIST SP 800-56a [SP-800-56a] specifies the co-factor elliptic-curve Diffie-Hellman key agreement scheme (co-factor ECDH) and can be instantiated with a suitable elliptic curve in short-Weierstrass form (that satisfies particular cryptographic criteria). While this completely specifies the internal workings of the key agreement scheme in question, this does not uniquely specify the input/output formats:

- a. The co-factor ECDH scheme is a two-party key agreement scheme that takes as inputs a private key d from one of the parties and a point Q' obtained from the other party and produces a shared key $K := h \cdot (d \cdot Q')$, where h and n are, respectively, the co-factor and the order of the base point of the curve in question and where Q' is a point of this curve. If this shared key K is the point at infinity O of the curve, the output is an error message;
- b. If the shared key K is an affine point of the curve, the output is the (raw) shared secret Z , which is the octet representation of the x -coordinate of K , using the FE2OS mapping of Appendix I.5, represented in tight-MSB/msb-order (see Appendix I.7).

(NOTE: A subsequent key derivation function (kdf) takes as inputs the shared secret Z and side information OtherInfo and produces as output an octet string of DerivedKeyingMaterial, where details depend on the used kdf in question. This step is out of scope.)

The inputs and outputs are uniquely determined by specifying the encodings of private keys, curve points, and the error message for this key agreement scheme.

The encodings below specify the use of instantiations of ECDH with COSE (see Section 10.3.1) and JOSE (see Section 10.3.2), where the encoding for a specific co-factor ECDH instantiation (i.e., with a specific short-Weierstrass curve) results by setting the "crv" parameter to the unique name of the underlying curve in question and the "alg" parameter to the unique name of the specific key agreement scheme instantiation (e.g., "ECDH25519" for the co-factor ECDH scheme defined in Section 4.1 and "ECDH448" for the scheme defined in Section 4.4). Note that, in this case, the "alg" name uniquely defines the curve (and, thereby, implicitly the underlying "crv" parameter).

10.3.1. Encoding of co-factor ECDH with COSE

Instantiations of co-factor ECDH used with COSE use the following encodings of inputs and outputs:

- a. Curve points and private keys are encoded as specified in Section 10.1.1, where the "crv" parameter is set to the unique name of the curve used with this particular instantiation of ECDH.

When using a COSE key for this algorithm, if the "alg" field is present, it MUST be set to the (unique) name of this particular instantiation of co-factor ECDH and the "crv" parameter MUST be set to the (unique) name of the corresponding curve; if the "key_ops" field is present, it MUST include "derive shared secret" for the private key.

10.3.2. Encoding of co-factor ECDH with JOSE

Instantiations of co-factor ECDH used with JOSE use the following encodings of inputs and outputs:

- a. Curve points and private keys are encoded as specified in Section 10.1.2, where the "crv" parameter is set to the unique name of the curve used with this particular instantiation of ECDH.

When using a JOSE key for this algorithm, if the "alg" field is present, it MUST be set to the (unique) name of this particular instantiation of co-factor ECDH and the "crv" parameter MUST be set to the (unique) name of the corresponding curve; if the "key_ops" field is present, it MUST include "derive shared secret" for the private key.

11. Using Wei25519 and Wei448 with PKIX and CMS

This section illustrates how to use the curves Wei25519 and Wei448 with ECDH and ECDSA with PKIX certificates (see [RFC5280] and [RFC5480]) and with CMS (see [RFC5652] and [RFC5753]).

11.1. Encoding of Short-Weierstrass Curves with PKIX

The `namedCurve` field in the `ECPParameters` field in the `SubjectPublicKeyInfo` structure [RFC5280] indicates the elliptic curve domain parameters for a specific curve, via a unique name of the curve in question (where these are the unique object identifiers `id-Wei25519` for the curve Wei25519 and `id-Wei448` for the curve Wei448).

Affine and compressed curve points are encoded using the "SEC1"-representation (see Note 2 of Appendix I.8), using the tight MSB/msb-ordering conventions. This is consistent with the representation in Section 2.2 of [RFC5480], after correcting for the error in [SEC1] (for the correction, see Note in Appendix H.1).

11.2. Encoding of ECDSA Instantiations with PKIX

ECDSA25519, as defined in Section 4.3, is the instantiation of ECDSA with SHA-256 and with curve Wei25519. With [RFC5480], ECDSA can be instantiated with suitable elliptic curves and hash functions. This allows support for ECDSA25519 by instantiating ECDSA with the curve Wei25519 and the hash function SHA256, where curve Wei25519 is identified by its object identifier `id-Wei25519` (see Section 11.1), where ECDSA with SHA256 is identified by the object identifier `id-ecdsa-with-SHA256` (see [RFC5480]), and where all other aspects are specified in [RFC5480].

ECDSA448, as defined in Section 4.4, is the instantiation of ECDSA with SHAKE256 with output size $d=512$ bits and with curve Wei448. With [RFC5480], ECDSA can be instantiated with suitable elliptic curves and hash functions. This allows support for ECDSA448 by instantiating ECDSA with the curve Wei448 and the hash function SHAKE256 with output size of $d=512$ bits, where curve Wei448 is identified by its object identifier `id-Wei448` (see Section 11.1), where ECDSA with SHAKE256 with output size of $d=512$ bits is identified by the object identifier `id-ecdsa-with-shake256` (see [RFC8692]), and where all other aspects are specified in [RFC5480].

11.3. Encoding of co-factor ECDH and Other Algorithms with PKIX

With [RFC5480], the `algorithm` field in the `SubjectPublicKeyInfo` structure indicates the algorithm and the elliptic curve domain parameters for a specific curve, where that specification defines

three algorithm identifiers (viz. `id-ecPublicKey`, `id-ecDH`, and `id-ecMQV`). Each of these algorithms can be instantiated with suitable elliptic curves, thereby allowing support for their use with the curves `Wei25519` and `Wei448`, where these curves are identified by their unique object identifiers `id-wei25519` and `id-wei448`, respectively, (see Section 11.1) and where all other aspects are specified in [RFC5480].

11.4. Encoding of Elliptic-Curve-Based Algorithms with CMS

With [RFC5753], elliptic-curve based algorithms should use one of the elliptic curve domain parameters specified in [RFC5480], where the unique name of each such curve is identified by the object identifier of this curve defined in that document. Each of these algorithms can be instantiated with suitable elliptic curves, thereby allowing support for their use with the curves `Wei25519` and `Wei448`, where these curves are identified by their unique object identifiers `id-wei25519` and `id-wei448`, respectively, (see Section 11.1) and where all other aspects are specified in [RFC5753].

12. IANA Considerations

Code points are requested for curves `Wei25519` and `Wei448` and their use with ECDSA and co-factor ECDH, using the representation conventions of this document.

New code points would be required in case one wishes to specify one or more other "offspring" protocols beyond those exemplified in Section 4.4. Specification hereof is, however, outside the scope of the current document.

12.1. OIDs for Use with PKIX and CMS

This section registers the following object identifiers for the curves introduced in this document:

- a. `id-Wei25519 OBJECT IDENTIFIER ::= TBD (Requested value: {iso(1) identified-organization(3) thawte (101) 108 });`
- b. `id-Wei448 OBJECT IDENTIFIER ::= TBD (Requested value: {iso(1) identified-organization(3) thawte (101) 109 });`

For a description of how these are used with PKIX certificates and CMS, see Section 11.

12.2. COSE/JOSE IANA Considerations for Wei25519

12.2.1. COSE Elliptic Curves Registration

This section registers the following value in the IANA "COSE Elliptic Curves" registry [IANA.COSE.Curves].

Name: Wei25519;

Value: TBD (Requested value: -1);

Key Type: EC2 or OKP;

Description: short-Weierstrass curve Wei25519;

Change Controller: IESG;

Reference: specified in Appendix E.3 of this specification; for encodings, see Section 10.1;

Recommended: Yes.

(Note that The "kty" value for Wei25519 may be "EC2" or "OKP".)

12.2.2. COSE Algorithms Registration (1/2)

This section registers the following value in the IANA "COSE Algorithms" registry [IANA.COSE.Algorithms].

Name: ECDSA25519;

Value: TBD (Requested value: -9);

Description: ECDSA with SHA-256 and curve Wei25519;

Change Controller: IESG;

Reference: specified in Section 4.3 of this specification; for encodings, see Section 10.2;

Recommended: Yes.

12.2.3. COSE Algorithms Registration (2/2)

This section registers the following value in the IANA "COSE Algorithms" registry [IANA.COSE.Algorithms].

Name: ECDH25519;

Value: TBD (Requested value: -24);

Description: NIST-compliant co-factor Diffie-Hellman w/ curve Wei25519 and key derivation function HKDF SHA256;

Change Controller: IESG;

Reference: specified in Section 4.1 of this specification; for encodings, see Section 10.3;

Recommended: Yes.

12.2.4. JOSE Elliptic Curves Registration

This section registers the following value in the IANA "JSON Web Key Elliptic Curve" registry [IANA.JOSE.Curves].

Curve Name: Wei25519;

Curve Description: short-Weierstrass curve Wei25519;

JOSE Implementation Requirements: Optional;

Change Controller: IESG;

Reference: specified in Appendix E.3 of this specification; for encodings, see Section 10.1.

(Note that The "kty" value for Wei25519 may be "EC" or "OKP".)

12.2.5. JOSE Algorithms Registration (1/2)

This section registers the following value in the IANA "JSON Web Signature and Encryption Algorithms" registry [IANA.JOSE.Algorithms].

Algorithm Name: ECDSA25519;

Algorithm Description: ECDSA using SHA-256 and curve Wei25519;

Algorithm Usage Locations: alg;

JOSE Implementation Requirements: Optional;

Change Controller: IESG;

Reference: specified in Section 4.3 of this specification; for encodings, see Section 10.2;

Algorithm Analysis Document(s): Section 4.3 of this specification.

12.2.6. JOSE Algorithms Registration (2/2)

This section registers the following value in the IANA "JSON Web Signature and Encryption Algorithms" registry [IANA.JOSE.Algorithms].

Algorithm Name: ECDH25519;

Algorithm Description: NIST-compliant co-factor Diffie-Hellman w/
curve Wei25519 and key derivation function HKDF SHA256;

Algorithm Usage Locations: alg;

JOSE Implementation Requirements: Optional;

Change Controller: IESG;

Reference: specified in Section 4.1 of this specification; for
encodings, see Section 10.3;

Algorithm Analysis Document(s): Section 4.1 of this specification.

12.3. COSE/JOSE IANA Considerations for Wei448

12.3.1. COSE Elliptic Curves Registration

This section registers the following value in the IANA "COSE Elliptic Curves" registry [IANA.COSE.Curves].

Name: Wei448;

Value: TBD (Requested value: -2);

Key Type: EC2 or OKP;

Description: short-Weierstrass curve Wei448;

Change Controller: IESG;

Reference: specified in Appendix M.3 of this specification; for
encodings, see Section 10.1;

Recommended: Yes.

(Note that The "kty" value for Wei448 may be "EC2" or "OKP".)

12.3.2. COSE Algorithms Registration (1/2)

This section registers the following value in the IANA "COSE Algorithms" registry [IANA.COSE.Algorithms].

Name: ECDSA448;

Value: TBD (Requested value: -48);

Description: ECDSA with SHAKE256 and curve Wei448;

Change Controller: IESG;

Reference: specified in Section 4.4 of this specification; for encodings, see Section 10.1;

Recommended: Yes.

12.3.3. COSE Algorithms Registration (2/2)

This section registers the following value in the IANA "COSE Algorithms" registry [IANA.COSE.Algorithms].

Name: ECDH448;

Value: TBD (Requested value: -49);

Description: NIST-compliant co-factor Diffie-Hellman w/ curve Wei448 and key derivation function HKDF SHA512;

Change Controller: IESG;

Reference: specified in Section 4.4 of this specification; for encodings, see Section 10.1; for key derivation, see Section 11.1 of [RFC8152];

Recommended: Yes.

12.3.4. JOSE Elliptic Curves Registration

This section registers the following value in the IANA "JSON Web Key Elliptic Curve" registry [IANA.JOSE.Curves].

Curve Name: Wei448;

Curve Description: short-Weierstrass curve Wei448;

JOSE Implementation Requirements: Optional;

Change Controller: IESG;

Reference: specified in Appendix M.3 of this specification; for encodings, see Section 10.1.

(Note that The "kty" value for Wei448 may be "EC" or "OKP".)

12.3.5. JOSE Algorithms Registration (1/2)

This section registers the following value in the IANA "JSON Web Signature and Encryption Algorithms" registry [IANA.JOSE.Algorithms].

Algorithm Name: ECDSA448;

Algorithm Description: ECDSA using SHAKE256 and curve Wei448;

Algorithm Usage Locations: alg;

JOSE Implementation Requirements: Optional;

Change Controller: IESG;

Reference: specified in Section 4.4 of this specification; for encodings, see Section 10.2;

Algorithm Analysis Document(s): Section 4.4 of this specification.

12.3.6. JOSE Algorithms Registration (2/2)

This section registers the following value in the IANA "JSON Web Signature and Encryption Algorithms" registry [IANA.JOSE.Algorithms].

Algorithm Name: ECDH448;

Algorithm Description: NIST-compliant co-factor Diffie-Hellman w/ curve Wei448;

Algorithm Usage Locations: alg;

JOSE Implementation Requirements: Optional;

Change Controller: IESG;

Reference: specified in Section 4.4 of this specification; for encodings, see Section 10.3;

Algorithm Analysis Document(s): Section 4.4 of this specification.

13. Acknowledgements

Thanks to Nikolas Rosener for discussions surrounding implementation details of the techniques described in this document and to Phillip Hallam-Baker for triggering inclusion of verbiage on the use of Montgomery ladders with recovery of the y-coordinate. Thanks to Stanislav Smyshlyaev and Vasily Nikolaev for their careful reviews.

Appendix A. Some (Non-Binary) Elliptic Curves

This section defines the three different curve models we consider, viz. short-Weierstrass curves, Montgomery curves, and twisted Edwards curves.

A.1. Curves in Short-Weierstrass Form

Let $GF(q)$ denote the finite field with q elements, where q is an odd prime power and where q is not divisible by three. Let $W_{\{a,b\}}$ be the Weierstrass curve with defining equation $Y^2 = X^3 + aX + b$, where a and b are elements of $GF(q)$ and where $4a^3 + 27b^2$ is nonzero. The points of $W_{\{a,b\}}$ are the ordered pairs (X, Y) whose coordinates are elements of $GF(q)$ and that satisfy the defining equation (the so-called affine points), together with the special point O (the so-called "point at infinity"). This set forms a group under addition, via the so-called "chord-and-tangent" rule, where the point at infinity serves as the identity element. See Appendix C.1 for details of the group operation.

A.2. Montgomery Curves

Let $GF(q)$ denote the finite field with q elements, where q is an odd prime power. Let $M_{\{A,B\}}$ be the Montgomery curve with defining equation $Bv^2 = u^3 + Au^2 + u$, where A and B are elements of $GF(q)$ and where A is unequal to $(+/-)2$ and where B is nonzero. The points of $M_{\{A,B\}}$ are the ordered pairs (u, v) whose coordinates are elements of $GF(q)$ and that satisfy the defining equation (the so-called affine points), together with the special point O (the so-called "point at infinity"). This set forms a group under addition, via the so-called "chord-and-tangent" rule, where the point at infinity serves as the identity element. See Appendix C.2 for details of the group operation.

A.3. Twisted Edwards Curves

Let $GF(q)$ denote the finite field with q elements, where q is an odd prime power. Let $E_{\{a,d\}}$ be the twisted Edwards curve with defining equation $ax^2 + y^2 = 1 + d^2x^2y^2$, where a and d are distinct nonzero elements of $GF(q)$. The points of $E_{\{a,d\}}$ are the ordered pairs (x, y) whose coordinates are elements of $GF(q)$ and that satisfy the defining equation (the so-called affine points). It can be shown that this set forms a group under addition if a is a square in $GF(q)$, whereas d is not, where the point $O := (0, 1)$ serves as the identity element. (Note that the identity element satisfies the defining equation.) See Appendix C.3 for details of the group operation.

An Edwards curve is a twisted Edwards curve with $a=1$.

Appendix B. Elliptic Curve Nomenclature and Finite Fields

This section provides brief background information on elliptic curves and finite fields that should be sufficient to understand constructions and examples in this document.

B.1. Elliptic Curve Nomenclature

The set of points of each curve defined in Appendix A forms a commutative group under addition (denoted by '+'). In Appendix C we specify the group laws, which depend on the curve model in question. For completeness, we here include some common elliptic curve nomenclature and basic properties (primarily so as to keep this document self-contained). These notions are mainly used in Appendix E and Appendix G and not essential for our exposition. This section can be skipped at first reading.

Any point P of a curve E is a generator of the cyclic subgroup $(P) := \{k*P \mid k = 0, 1, 2, \dots\}$ of the curve. (Here, $k*P$ denotes the sum of k copies of P , where $0*P$ is the identity element O of the curve; $k*P$ is commonly referred to as scalar multiplication of P by k .) If (P) has cardinality l , then l is called the order of P and l is the smallest positive integer so that $l*P=O$. The order of curve E is the cardinality of the set of its points, commonly denoted by $|E|$. A curve is cyclic if it is generated by some point of this curve. All curves of prime order are cyclic, while all curves of order $h*n$, where n is a large prime number and where h is a small number (the so-called co-factor), have a large cyclic subgroup of prime order n . In this case, a generator of order n is called a base point, commonly denoted by G , while a point of order dividing h is said to be in the small subgroup (or said to be a low-order point). For curves of prime order, this small subgroup is the singleton set, consisting of only the identity element O . A point that is not in the small subgroup is said to be a high-order point (since it has order at least n). A point P of the curve is in the small subgroup if $h*P=O$ (and is a high-order point otherwise); this point has order n if $n*P=O$ and if it is not the identity element O . (The latter order check is commonly called full public key validation.)

If R is a point of the curve that is also contained in (P) , there is a unique integer k in the interval $[0, l-1]$ so that $R=k*P$, where l is the order of P . This number is called the discrete logarithm of R to the base P . The discrete logarithm problem is the problem of finding the discrete logarithm of R to the base P for any two points P and R of the curve, if such a number exists.

Random points R of (P) , where P has order l , can be computed by generating a random integer k in the interval $[0, l-1]$ and by

subsequently computing $R:=k*P$, where R has order $l/\gcd(k,l)$. In particular, if P is a high-order point, then so is R , unless k is a multiple of n (in which case R is a low-order point). For methods for generating k , see Appendix P.

If P is a fixed base point G of the curve, the pair $(k, R:=k*G)$ is commonly called a public-private key pair, the integer k the private key, and the point R the corresponding public key. The private key k can be represented as an integer in the interval $[0,n-1]$, where G has order n . If this representation is nonzero, R has order n ; otherwise, it has order one and is the identity element O of the curve.

In this document, a quadratic twist of a curve E defined over a field $GF(q)$ is a specific curve E' related to E defined over the same field, with cardinality $|E'|$, where $|E|+|E'|=2*(q+1)$. If E is a curve in one of the curve models specified in this document, a quadratic twist of this curve can be expressed using the same curve model, although (naturally) with its own curve parameters. Two curves E and E' defined over a field $GF(q)$ are said to be isogenous if these have the same order and are said to be isomorphic if these have the same group structure. Note that isomorphic curves have necessarily the same order and are, thus, a special type of isogenous curves. Further details are out of scope.

Weierstrass curves can have prime order, whereas Montgomery curves and twisted Edwards curves always have an order that is a multiple of four (and, thereby, a small subgroup of cardinality four).

An ordered pair (x, y) whose coordinates are elements of $GF(q)$ can be associated with any ordered triple of the form $[x*z: y*z: z]$, where z is a nonzero element of $GF(q)$, and can be uniquely recovered from such a representation. The latter representation is commonly called a representation in projective coordinates. Sometimes, yet other representations are useful (e.g., representation in Jacobian coordinates). Further details are out of scope.

The group laws in Appendix C are mostly expressed in terms of affine points, but can also be expressed in terms of the representation of these points in projective coordinates, thereby allowing clearing of denominators. The group laws may also involve non-affine points (such as the point at infinity O of a Weierstrass curve or of a Montgomery curve). Those can also be represented in projective coordinates. Further details are out of scope.

B.2. Finite Fields

The field $GF(q)$, where q is a prime power, is defined as follows.

If $q=p$ is a prime number, the field $GF(p)$ consists of the integers in the interval $[0,p-1]$ and two binary operations on this set: addition and multiplication modulo p . This field is commonly called a prime field.

If $q=p^m$, where p is a prime number and where $m>0$, the field $GF(q)$ is defined in terms of an irreducible polynomial $f(z)$ in z of degree m with coefficients in $GF(p)$ (i.e., $f(z)$ cannot be written as the product of two polynomials in z of lower degree with coefficients in $GF(p)$): in this case, $GF(q)$ consists of the polynomials in z of degree smaller than m with coefficients in $GF(p)$ and two binary operations on this set: polynomial addition and polynomial multiplication modulo the irreducible polynomial $f(z)$. By definition, each element x of $GF(q)$ is a polynomial in z of degree smaller than m and can, therefore, be uniquely represented as a vector $(x_{m-1}, x_{m-2}, \dots, x_1, x_0)$ of length m with coefficients in $GF(p)$, where x_i is the coefficient of z^i of polynomial x . Note that this representation depends on the irreducible polynomial $f(z)$ of the field $GF(p^m)$ in question (which is often fixed in practice). Note that $GF(q)$ contains the prime field $GF(p)$ as a subset. If $m=1$, the definitions of $GF(p)$ and $GF(p^1)$ above coincide, since each nonzero element of $GF(p)$ can be viewed as a polynomial in z of degree zero. If $m>1$ (i.e., if q is a strict prime power), then $GF(q)$ is called a (nontrivial) extension field of $GF(p)$. The number p is called the characteristic of $GF(q)$.

A field element y is called a square in $GF(q)$ if it can be expressed as $y=x^2$ for some x in $GF(q)$; it is called a non-square in $GF(q)$ otherwise. If y is a square in $GF(q)$, we denote by $\text{sqrt}(y)$ one of its square roots (the other one being $-\text{sqrt}(y)$). For methods for computing square roots and inverses in $GF(q)$ - if these exist - see Appendix K.1 and Appendix K.2, respectively. For methods for mapping a nonzero field element that is not a square in $GF(q)$ to a point of a curve, see Appendix K.3 (or see Appendix K.4, if one wishes to always obtain a high-order point of the curve in question).

NOTE: The curves in Appendix E and Appendix G are all defined over a prime field $GF(p)$, thereby reducing all operations to simple modular integer arithmetic. Strictly speaking we could, therefore, have refrained from introducing extension fields. Nevertheless, we included the more general exposition, so as to accommodate potential introduction of new curves that are defined over a (nontrivial) extension field at some point in the future. This includes curves proposed for post-quantum isogeny-based schemes, which are defined

over a quadratic extension field (i.e., where $q:=p^2$), and elliptic curves used with pairing-based cryptography. The exposition in either case is almost the same and now automatically yields, e.g., data conversion routines for any finite field object (see Appendix I). Readers not interested in this, could simply view all fields as prime fields.

Appendix C. Elliptic Curve Group Operations

This section specifies group operations for elliptic curves in short-Weierstrass form, for Montgomery curves, and for twisted Edwards curves.

C.1. Group Laws for Weierstrass Curves

For each point P of the Weierstrass curve $W_{\{a,b\}}$, the point at infinity O serves as identity element, i.e., $P + O = O + P = P$.

For each affine point $P:=(X, Y)$ of the Weierstrass curve $W_{\{a,b\}}$, the point $-P$ is the point $(X, -Y)$ and one has $P + (-P) = O$ (i.e., $-P$ is the inverse of P). For the point at infinity O , one has $-O:=O$.

Let $P_1:=(X_1, Y_1)$ and $P_2:=(X_2, Y_2)$ be distinct affine points of the Weierstrass curve $W_{\{a,b\}}$ and let $Q:=P_1 + P_2$, where Q is not the identity element. Then $Q:=(X, Y)$, where

$$X + X_1 + X_2 = \lambda^2 \text{ and } Y + Y_1 = \lambda*(X_1 - X), \text{ where}$$

$$\lambda := (Y_2 - Y_1)/(X_2 - X_1).$$

Let $P:=(X_1, Y_1)$ be an affine point of the Weierstrass curve $W_{\{a,b\}}$ and let $Q:=2*P$, where Q is not the identity element. Then $Q:=(X, Y)$, where

$$X + 2*X_1 = \lambda^2 \text{ and } Y + Y_1 = \lambda*(X_1 - X), \text{ where}$$

$$\lambda := (3*X_1^2 + a)/(2*Y_1).$$

From the group laws above it follows that if $P=(X, Y)$, $P_1=(X_1, Y_1)$, and $P_2=(X_2, Y_2)$ are distinct affine points of the Weierstrass curve $W_{\{a,b\}}$ with $P_2:=P+P_1$ and if Y is nonzero, then the Y -coordinate of P_1 can be expressed in terms of the X -coordinates of P , P_1 , and P_2 , and the Y -coordinate of P , since

$$2*Y*Y_1=(X*X_1+a)*(X+X_1)+2*b-X_2*(X-X_1)^2.$$

This property allows recovery of the Y -coordinate of a point $P_1=k*P$ that is computed via the so-called Montgomery ladder, where P is an

affine point with nonzero Y-coordinate (i.e., it does not have order two). For future reference, note that the expression above uniquely determines the X-coordinate of P_2 in terms of the X-coordinates of P and P_1 and the product of their Y-coordinates. Further details are out of scope.

C.2. Group Laws for Montgomery Curves

For each point P of the Montgomery curve $M_{\{A,B\}}$, the point at infinity O serves as identity element, i.e., $P + O = O + P = P$.

For each affine point $P := (u, v)$ of the Montgomery curve $M_{\{A,B\}}$, the point $-P$ is the point $(u, -v)$ and one has $P + (-P) = O$ (i.e., $-P$ is the inverse of P). For the point at infinity O , one has $-O := O$.

Let $P_1 := (u_1, v_1)$ and $P_2 := (u_2, v_2)$ be distinct affine points of the Montgomery curve $M_{\{A,B\}}$ and let $Q := P_1 + P_2$, where Q is not the identity element. Then $Q := (u, v)$, where

$$u + u_1 + u_2 = B \cdot \lambda^2 - A \text{ and } v + v_1 = \lambda \cdot (u_1 - u), \text{ where} \\ \lambda := (v_2 - v_1) / (u_2 - u_1).$$

Let $P := (u_1, v_1)$ be an affine point of the Montgomery curve $M_{\{A,B\}}$ and let $Q := 2 \cdot P$, where Q is not the identity element. Then $Q := (u, v)$, where

$$u + 2 \cdot u_1 = B \cdot \lambda^2 - A \text{ and } v + v_1 = \lambda \cdot (u_1 - u), \text{ where} \\ \lambda := (3 \cdot u_1^2 + 2 \cdot A \cdot u_1 + 1) / (2 \cdot B \cdot v_1).$$

From the group laws above it follows that if $P = (u, v)$, $P_1 = (u_1, v_1)$, and $P_2 = (u_2, v_2)$ are distinct affine points of the Montgomery curve $M_{\{A,B\}}$ with $P_2 := P + P_1$ and if v is nonzero, then the v -coordinate of P_1 can be expressed in terms of the u -coordinates of P , P_1 , and P_2 , and the v -coordinate of P , since

$$2 \cdot B \cdot v \cdot v_1 = (u \cdot u_1 + 1) \cdot (u + u_1 + 2 \cdot A) - 2 \cdot A - u_2 \cdot (u - u_1)^2.$$

This property allows recovery of the v -coordinate of a point $P_1 = k \cdot P$ that is computed via the so-called Montgomery ladder, where P is an affine point with nonzero v -coordinate (i.e., it does not have order two). For future reference, note that the expression above uniquely determines the u -coordinate of P_2 in terms of the u -coordinates of P and P_1 and the product of their v -coordinates. Further details are out of scope.

C.3. Group Laws for Twisted Edwards Curves

Note: The group laws below hold for twisted Edwards curves $E_{\{a,d\}}$ where a is a square in $GF(q)$, whereas d is not. In this case, the addition formulae below are defined for each pair of points, without exceptions. Generalizations of this group law to other twisted Edwards curves are out of scope.

For each point P of the twisted Edwards curve $E_{\{a,d\}}$, the point $O:=(0,1)$ serves as identity element, i.e., $P + O = O + P = P$.

For each point $P:=(x, y)$ of the twisted Edwards curve $E_{\{a,d\}}$, the point $-P$ is the point $(-x, y)$ and one has $P + (-P) = O$ (i.e., $-P$ is the inverse of P).

Let $P_1:=(x_1, y_1)$ and $P_2:=(x_2, y_2)$ be points of the twisted Edwards curve $E_{\{a,d\}}$ and let $Q:=P_1 + P_2$. Then $Q:=(x, y)$, where

$$x = (x_1*y_2 + x_2*y_1)/(1 + d*x_1*x_2*y_1*y_2) \text{ and}$$

$$y = (y_1*y_2 - a*x_1*x_2)/(1 - d*x_1*x_2*y_1*y_2).$$

Let $P:=(x_1, y_1)$ be a point of the twisted Edwards curve $E_{\{a,d\}}$ and let $Q:=2*P$. Then $Q:=(x, y)$, where

$$x = (2*x_1*y_1)/(1 + d*x_1^2*y_1^2) \text{ and}$$

$$y = (y_1^2 - a*x_1^2)/(1 - d*x_1^2*y_1^2).$$

Note that one can use the formulae for point addition for point doubling, taking inverses, and adding the identity element as well (i.e., the point addition formulae are uniform and complete (subject to our Note above)).

From the group laws above (subject to our Note above) it follows that if $P=(x, y)$, $P_1=(x_1, y_1)$, and $P_2=P+(x_2, y_2)$ are points of the twisted Edwards curve $E_{\{a,d\}}$ with $P_2:=P+P_1$ and if x is nonzero, then the x -coordinate of P_1 can be expressed in terms of the y -coordinates of P , P_1 , and P_2 , and the x -coordinate of P , since

$$x*x_1*(a-d*y*y_1*y_2)=y*y_1-y_2.$$

(Here, observe that $a-d*y*y_1*y_2$ is nonzero per our Note above.) This property allows recovery of the x -coordinate of a point $P_1=k*P$ that is computed via the so-called Montgomery ladder, where P is an affine point with nonzero x -coordinate (i.e., it does not have order one or two). For future reference, note that the group law (subject to our Note above) uniquely determines the y -coordinate of P_2 in terms of

the y-coordinates of P and P1 and the product of their x-coordinates. Further details are out of scope.

Appendix D. Relationships Between Curve Models

The non-binary curves specified in Appendix A are expressed in different curve models, viz. as curves in short-Weierstrass form, as Montgomery curves, or as twisted Edwards curves. These curve models are related, as follows.

D.1. Mapping between Twisted Edwards Curves and Montgomery Curves

One can map points of the Montgomery curve $M_{\{A,B\}}$ to points of the twisted Edwards curve $E_{\{a,d\}}$, where $a:=(A+2)/B$ and $d:=(A-2)/B$ and, conversely, map points of the twisted Edwards curve $E_{\{a,d\}}$ to points of the Montgomery curve $M_{\{A,B\}}$, where $A:=2*(a+d)/(a-d)$ and where $B:=4/(a-d)$. For twisted Edwards curves we consider (i.e., those where a is a square in $GF(q)$, whereas d is not), this defines a one-to-one correspondence, which - in fact - is an isomorphism between $M_{\{A,B\}}$ and $E_{\{a,d\}}$, thereby showing that, e.g., the discrete logarithm problem in either curve model is equally hard.

For the Montgomery curves and twisted Edwards curves we consider, the mapping from $M_{\{A,B\}}$ to $E_{\{a,d\}}$ is defined by mapping the point at infinity O and the point $(0, 0)$ of order two of $M_{\{A,B\}}$ to, respectively, the point $(0, 1)$ and the point $(0, -1)$ of order two of $E_{\{a,d\}}$, while mapping each other point (u, v) of $M_{\{A,B\}}$ to the point $(x,y):=(u/v,(u-1)/(u+1))$ of $E_{\{a,d\}}$. The inverse mapping from $E_{\{a,d\}}$ to $M_{\{A,B\}}$ is defined by mapping the point $(0, 1)$ and the point $(0, -1)$ of order two of $E_{\{a,d\}}$ to, respectively, the point at infinity O and the point $(0, 0)$ of order two of $M_{\{A,B\}}$, while each other point (x, y) of $E_{\{a,d\}}$ is mapped to the point $(u,v):=((1+y)/(1-y),(1+y)/((1-y)*x))$ of $M_{\{A,B\}}$.

Implementations may take advantage of this mapping to carry out elliptic curve group operations originally defined for a twisted Edwards curve on the corresponding Montgomery curve, or vice-versa, and translating the result back to the original curve, thereby potentially allowing code reuse.

D.2. Mapping between Montgomery Curves and Weierstrass Curves

One can map points of the Montgomery curve $M_{\{A,B\}}$ to points of the Weierstrass curve $W_{\{a,b\}}$, where $a:=(3-A^2)/(3*B^2)$ and $b:=(2*A^3-9*A)/(27*B^3)$. This defines a one-to-one correspondence, which - in fact - is an isomorphism between $M_{\{A,B\}}$ and $W_{\{a,b\}}$, thereby showing that, e.g., the discrete logarithm problem in either curve model is equally hard.

The mapping from $M_{\{A,B\}}$ to $W_{\{a,b\}}$ is defined by mapping the point at infinity O of $M_{\{A,B\}}$ to the point at infinity O of $W_{\{a,b\}}$, while mapping each other point (u,v) of $M_{\{A,B\}}$ to the point $(X,Y) := ((u+A/3)/B, v/B)$ of $W_{\{a,b\}}$.

Note that not all Weierstrass curves can be injectively mapped to Montgomery curves, since the latter have a point of order two and the former may not. In particular, if a Weierstrass curve has prime order, such as is the case with the so-called "NIST prime curves", this inverse mapping is not defined.

If the Weierstrass curve $W_{\{a,b\}}$ has a point $(\alpha,0)$ of order two and $c := a + 3(\alpha)^2$ is a square in $GF(q)$, one can map points of this curve to points of the Montgomery curve $M_{\{A,B\}}$, where $A := 3\alpha/\gamma$ and $B := 1/\gamma$ and where γ is any square root of c . In this case, the mapping from $W_{\{a,b\}}$ to $M_{\{A,B\}}$ is defined by mapping the point at infinity O of $W_{\{a,b\}}$ to the point at infinity O of $M_{\{A,B\}}$, while mapping each other point (X,Y) of $W_{\{a,b\}}$ to the point $(u,v) := ((X-\alpha)/\gamma, Y/\gamma)$ of $M_{\{A,B\}}$. As before, this defines a one-to-one correspondence, which - in fact - is an isomorphism between $W_{\{a,b\}}$ and $M_{\{A,B\}}$. It is easy to see that the mapping from $W_{\{a,b\}}$ to $M_{\{A,B\}}$ and that from $M_{\{A,B\}}$ to $W_{\{a,b\}}$ (if defined) are each other's inverse.

This mapping can be used to implement elliptic curve group operations originally defined for a twisted Edwards curve or for a Montgomery curve using group operations for the corresponding elliptic curve in short-Weierstrass form and translating the result back to the original curve, thereby potentially allowing code reuse.

Note that implementations for elliptic curves with short-Weierstrass form that hard-code the domain parameter a to $a = -3$ (which value is known to allow more efficient implementations) cannot always be used this way, since the curve $W_{\{a,b\}}$ resulting from an isomorphic mapping cannot always be expressed as a Weierstrass curve with $a = -3$ via a coordinate transformation. For more details, see Appendix F.

D.3. Mapping between Twisted Edwards Curves and Weierstrass Curves

One can map points of the twisted Edwards curve $E_{\{a,d\}}$ to points of the Weierstrass curve $W_{\{a,b\}}$, via function composition, where one uses the isomorphic mapping between twisted Edwards curves and Montgomery curves of Appendix D.1 and the one between Montgomery and Weierstrass curves of Appendix D.2. Obviously, one can use function composition (now using the respective inverses - if these exist) to realize the inverse of this mapping.

Appendix E. Curve25519 and Cousins

This section introduces curves related to Curve25519 and explains their relationships.

E.1. Curve Definition and Alternative Representations

The elliptic curve Curve25519 is the Montgomery curve $M_{\{A,B\}}$ defined over the prime field $GF(p)$, with $p:=2^{\{255\}}-19$, where $A:=486662$ and $B:=1$. This curve has order $h*n$, where $h=8$ and where n is a prime number. For this curve, A^2-4 is not a square in $GF(p)$, whereas $A+2$ is. The quadratic twist of this curve has order $h1*n1$, where $h1=4$ and where $n1$ is a prime number. For this curve, the base point is the point (Gu, Gv) , where $Gu=9$ and where Gv is an odd integer in the interval $[0, p-1]$.

This curve has the same group structure as (is "isomorphic" to) the twisted Edwards curve $E_{\{a,d\}}$ defined over $GF(p)$, with as base point the point (Gx, Gy) , where parameters are as specified in Appendix E.3. This curve is denoted as Edwards25519. For this curve, the parameter a is a square in $GF(p)$, whereas d is not, so the group laws of Appendix C.3 apply.

The curve is also isomorphic to the elliptic curve $W_{\{a,b\}}$ in short-Weierstrass form defined over $GF(p)$, with as base point the point (GX, GY) , where parameters are as specified in Appendix E.3. This curve is denoted as Wei25519. For this curve, the parameter b is a square in $GF(p)$. (For future reference, we note that this curve has no affine points with x-coordinate -1 .)

E.2. Switching between Alternative Representations

Each affine point (u, v) of Curve25519 corresponds to the point $(X, Y):=(u + A/3, v)$ of Wei25519, while the point at infinity of Curve25519 corresponds to the point at infinity of Wei25519. (Here, we used the mappings of Appendix D.2 and that $B=1$.) Under this mapping, the base point (Gu, Gv) of Curve25519 corresponds to the base point (GX, GY) of Wei25519. The inverse mapping maps the affine point (X, Y) of Wei25519 to $(u, v):=(X - A/3, Y)$ of Curve25519, while mapping the point at infinity of Wei25519 to the point at infinity of Curve25519. Note that this mapping involves a simple shift of the first coordinate and can be implemented via integer-only arithmetic as a shift of $(p+A)/3$ for the isomorphic mapping and a shift of $-(p+A)/3$ for its inverse, where $\delta=(p+A)/3$ is the element of $GF(p)$ defined by

```
delta 19298681539552699237261830834781317975544997444273427339909597
      334652188435537
```

```
(=0x2aaaaaaaa aaaaaaaaa aaaaaaaaa aaaaaaaaa aaaaaaaaa aaaaaaaaa
aaaaaaaa aaad2451).
```

(Note that, depending on the implementation details of the field arithmetic, one may have to shift the result by $+p$ or $-p$ if this integer is not in the interval $[0, p-1]$.)

The curve Edwards25519 is isomorphic to the curve Curve25519, where the base point (G_u, G_v) of Curve25519 corresponds to the base point (G_x, G_y) of Edwards25519 and where the point at infinity and the point $(0, 0)$ of order two of Curve25519 correspond to, respectively, the point $(0, 1)$ and the point $(0, -1)$ of order two of Edwards25519 and where each other point (u, v) of Curve25519 corresponds to the point $(c*u/v, (u-1)/(u+1))$ of Edwards25519, where c is the element of $GF(p)$ defined by

```
c  sqrt(-(A+2)/B)
```

```
51042569399160536130206135233146329284152202253034631822681833788
666877215207
```

```
(=0x70d9120b 9f5ff944 2d84f723 fc03b081 3a5e2c2e b482e57d
3391fb55 00ba81e7).
```

(Here, we used the mapping of Appendix D.1 and normalized this using the mapping of Appendix F.1 (where the element s of that appendix is set to c above).) The inverse mapping from Edwards25519 to Curve25519 is defined by mapping the point $(0, 1)$ and the point $(0, -1)$ of order two of Edwards25519 to, respectively, the point at infinity and the point $(0, 0)$ of order two of Curve25519 and having each other point (x, y) of Edwards25519 correspond to the point $((1 + y)/(1 - y), c*(1 + y)/((1-y)*x))$ of Curve25519.

The curve Edwards25519 is isomorphic to the Weierstrass curve Wei25519, where the base point (G_x, G_y) of Edwards25519 corresponds to the base point (G_X, G_Y) of Wei25519 and where the identity element $(0, 1)$ and the point $(0, -1)$ of order two of Edwards25519 correspond to, respectively, the point at infinity O and the point $(A/3, 0)$ of order two of Wei25519 and where each other point (x, y) of Edwards25519 corresponds to the point $(X, Y) := ((1+y)/(1-y) + A/3, c*(1+y)/((1-y)*x))$ of Wei25519, where c was defined before. (Here, we used the mapping of Appendix D.3.) The inverse mapping from Wei25519 to Edwards25519 is defined by mapping the point at infinity O and the point $(A/3, 0)$ of order two of Wei25519 to, respectively, the identity element $(0, 1)$ and the point $(0, -1)$ of order two of Edwards25519 and having each other point (X, Y) of Wei25519 correspond to the point $(c*(X-A/3)/Y, (X-A/3-1)/(X-A/3+1))$ of Edwards25519.

Note that these mappings can be easily realized if points are represented in projective coordinates, using a few field multiplications only, thus allowing switching between alternative curve representations with negligible relative incremental cost.

E.3. Domain Parameters

The parameters of the Montgomery curve and the corresponding isomorphic curves in twisted Edwards curve and short-Weierstrass form are as indicated below. Here, the domain parameters of the Montgomery curve Curve25519 and of the twisted Edwards curve Edwards25519 are as specified in [RFC7748]; the domain parameters of Wei25519 are "new".

General parameters (for all curve models):

```

Appendix F. Further Mappings

The non-binary curves specified in Appendix A are expressed in different curve models, viz. as curves in short-Weierstrass form, as Montgomery curves, or as twisted Edwards curves. In Appendix D we already described relationships between these various curve models. Further mappings exist between elliptic curves within the same curve model. These can be exploited to force some of the domain parameters to specific values that allow for a more efficient implementation of the addition formulae.

F.1. Isomorphic Mapping between Twisted Edwards Curves

One can map points of the twisted Edwards curve $E_{\{a,d\}}$ to points of the twisted Edwards curve $E_{\{a',d'\}}$, where $a:=a'*s^2$ and $d:=d'*s^2$ for some nonzero element s of $GF(q)$. This defines a one-to-one correspondence, which - in fact - is an isomorphism between $E_{\{a,d\}}$ and $E_{\{a',d'\}}$.

The mapping from $E_{\{a,d\}}$ to $E_{\{a',d'\}}$ is defined by mapping the point (x,y) of $E_{\{a,d\}}$ to the point $(x',y'):= (s*x, y)$ of $E_{\{a',d'\}}$. The inverse mapping from $E_{\{a',d'\}}$ to $E_{\{a,d\}}$ is defined by mapping the point (x',y') of $E_{\{a',d'\}}$ to the point $(x,y):= (x'/s, y')$ of $E_{\{a,d\}}$.

Implementations may take advantage of this mapping to carry out elliptic curve group operations originally defined for a twisted Edwards curve with generic domain parameters a and d on a corresponding isomorphic twisted Edwards curve with domain parameters a' and d' that have a more special form and that are known to allow for more efficient implementations of addition laws and translating the result back to the original curve. In particular, it is known that such efficiency improvements exist if $a':=(+/-)1$ (see [tEd-Formulas]).

F.2. Isomorphic Mapping between Montgomery Curves

One can map points of the Montgomery curve $M_{\{A,B\}}$ to points of the Montgomery curve $M_{\{A',B'\}}$, where $A:=A'$ and $B:=B'*s^2$ for some nonzero element s of $GF(q)$. This defines a one-to-one correspondence, which - in fact - is an isomorphism between $M_{\{A,B\}}$ and $M_{\{A',B'\}}$.

The mapping from $M_{\{A,B\}}$ to $M_{\{A',B'\}}$ is defined by mapping the point at infinity O of $M_{\{A,B\}}$ to the point at infinity O of $M_{\{A',B'\}}$,

while mapping each other point (u,v) of $M_{\{A,B\}}$ to the point $(u',v') := (u, s*v)$ of $M_{\{A',B'\}}$. The inverse mapping from $M_{\{A',B'\}}$ to $M_{\{A,B\}}$ is defined by mapping the point at infinity O of $M_{\{A',B'\}}$ to the point at infinity O of $M_{\{A,B\}}$, while mapping each other point (u',v') of $M_{\{A',B'\}}$ to the point $(u,v) := (u', v'/s)$ of $M_{\{A,B\}}$.

One can also map points of the Montgomery curve $M_{\{A,B\}}$ to points of the Montgomery curve $M_{\{A',B'\}}$, where $A' := -A$ and $B' := -B$. This defines a one-to-one correspondence, which - in fact - is an isomorphism between $M_{\{A,B\}}$ and $M_{\{A',B'\}}$.

In this case, the mapping from $M_{\{A,B\}}$ to $M_{\{A',B'\}}$ is defined by mapping the point at infinity O of $M_{\{A,B\}}$ to the point at infinity O of $M_{\{A',B'\}}$, while mapping each other point (u,v) of $M_{\{A,B\}}$ to the point $(u',v') := (-u,v)$ of $M_{\{A',B'\}}$. The inverse mapping from $M_{\{A',B'\}}$ to $M_{\{A,B\}}$ is defined by mapping the point at infinity O of $M_{\{A',B'\}}$ to the point at infinity O of $M_{\{A,B\}}$, while mapping each other point (u',v') of $M_{\{A',B'\}}$ to the point $(u,v) := (-u',v')$ of $M_{\{A,B\}}$.

Implementations may take advantage of these mappings to carry out elliptic curve groups operations originally defined for a Montgomery curve with generic domain parameters A and B on a corresponding isomorphic Montgomery curve with domain parameters A' and B' that have a more special form and that are known to allow for more efficient implementations of addition laws and translating the result back to the original curve. In particular, it is known that such efficiency improvements exist if B' assumes a small absolute value, such as $B' := (+/-)1$. (see [Mont-Ladder]).

F.3. Isomorphic Mapping between Weierstrass Curves

One can map points of the Weierstrass curve $W_{\{a,b\}}$ to points of the Weierstrass curve $W_{\{a',b'\}}$, where $a' := a*s^4$ and $b' := b*s^6$ for some nonzero element s of $GF(q)$. This defines a one-to-one correspondence, which - in fact - is an isomorphism between $W_{\{a,b\}}$ and $W_{\{a',b'\}}$.

The mapping from $W_{\{a,b\}}$ to $W_{\{a',b'\}}$ is defined by mapping the point at infinity O of $W_{\{a,b\}}$ to the point at infinity O of $W_{\{a',b'\}}$, while mapping each other point (X,Y) of $W_{\{a,b\}}$ to the point $(X',Y') := (X*s^2, Y*s^3)$ of $W_{\{a',b'\}}$. The inverse mapping from $W_{\{a',b'\}}$ to $W_{\{a,b\}}$ is defined by mapping the point at infinity O of $W_{\{a',b'\}}$ to the point at infinity O of $W_{\{a,b\}}$, while mapping each other point (X',Y') of $W_{\{a',b'\}}$ to the point $(X,Y) := (X'/s^2, Y'/s^3)$ of $W_{\{a,b\}}$.

Implementations may take advantage of this mapping to carry out elliptic curve group operations originally defined for a Weierstrass curve with generic domain parameters a and b on a corresponding isomorphic Weierstrass curve with domain parameter a' and b' that have a more special form and that are known to allow for more efficient implementations of addition laws and translating the result back to the original curve. In particular, it is known that such efficiency improvements exist if $a' = -3 \pmod{p}$, where p is the characteristic of $\text{GF}(q)$, and one uses so-called Jacobian coordinates with a particular projective version of the addition laws of Appendix C.1. While not all Weierstrass curves can be put into this form, all traditional NIST curves have domain parameter $a = -3$, while all Brainpool curves [RFC5639] are isomorphic to a Weierstrass curve of this form via the above mapping.

Note that implementations for elliptic curves with short-Weierstrass form that hard-code the domain parameter a to $a = -3$ cannot always be used this way, since the curve $W_{\{a,b\}}$ cannot always be expressed in terms of a Weierstrass curve with $a' = -3$ via a coordinate transformation: this only holds if a'/a is a fourth power in $\text{GF}(q)$ (see Section 3.1.5 of [GECC]). However, even in this case, one can still express the curve $W_{\{a,b\}}$ as a Weierstrass curve with a small domain parameter value a' , thereby still allowing a more efficient implementation than with a general domain parameter value a .

F.4. Isogenous Mapping between Weierstrass Curves

One can still map points of the Weierstrass curve $W_{\{a,b\}}$ to points of the Weierstrass curve $W_{\{a',b'\}}$, where $a' = -3 \pmod{p}$ and where p is the characteristic of $\text{GF}(q)$, even if a'/a is not a fourth power in $\text{GF}(q)$. In that case, this mapping cannot be an isomorphism (see Appendix F.3). Instead, the mapping is a so-called isogeny (or homomorphism). Since most elliptic curve operations process points of prime order or use so-called "co-factor multiplication", in practice the resulting mapping has similar properties as an isomorphism. In particular, one can still take advantage of this mapping to carry out elliptic curve group operations originally defined for a Weierstrass curve with domain parameter a unequal to $-3 \pmod{p}$ on a corresponding isogenous Weierstrass curve with domain parameter $a' = -3 \pmod{p}$ and translating the result back to the original curve.

In this case, the mapping from $W_{\{a,b\}}$ to $W_{\{a',b'\}}$ is defined by mapping the point at infinity O of $W_{\{a,b\}}$ to the point at infinity O of $W_{\{a',b'\}}$, while mapping each other point (X,Y) of $W_{\{a,b\}}$ to the point $(X',Y') := (u(X)/w(X)^2, Y*v(X)/w(X)^3)$ of $W_{\{a',b'\}}$. Here, $u(X)$, $v(X)$, and $w(X)$ are polynomials in X that depend on the isogeny in question, as do domain parameters a' and b' . The inverse mapping

from $W_{\{a',b'\}}$ to $W_{\{a,b\}}$ is again an isogeny (called the dual isogeny) and defined by mapping the point at infinity O of $W_{\{a',b'\}}$ to the point at infinity O of $W_{\{a,b\}}$, while mapping each other point (X', Y') of $W_{\{a',b'\}}$ to the point $(X,Y):=(u'(X')/w'(X')^2,Y'*v'(X')/w'(X')^3)$ of $W_{\{a,b\}}$, where -- again -- $u'(X')$, $v'(X')$, and $w'(X')$ are polynomials in X' that depend on the isogeny in question. These mappings have the property that their composition is not the identity mapping (as was the case with the isomorphic mappings discussed in Appendix F.3), but rather a fixed multiple hereof: if this multiple is l then the isogeny is called an isogeny of degree l (or l -isogeny) and u , v , and w (and, similarly, u' , v' , and w') are polynomials of degrees l , $3*(l-1)/2$, and $(l-1)/2$, respectively. Note that an isomorphism is simply an isogeny of degree $l=1$. Details of how to determine isogenies are out of the scope of this document. The above formulas assume that the isogeny has odd degree (i.e., l is odd); detailed formulas for even-degree isogenies are similar, but out of scope.

Implementations may take advantage of this mapping to carry out elliptic curve group operations originally defined for a Weierstrass curve with a generic domain parameter a on a corresponding isogenous Weierstrass curve with domain parameter $a'=-3 \pmod{p}$, where one can use so-called Jacobian coordinates with a particular projective version of the addition laws of Appendix C.1. Since all traditional NIST curves have domain parameter $a=-3$, while all Brainpool curves [RFC5639] are isomorphic to a Weierstrass curve of this form, this allows taking advantage of existing implementations for these curves that may have a hardcoded $a=-3 \pmod{p}$ domain parameter, provided one switches back and forth to this curve form using the isogenous mapping in question.

Note that isogenous mappings can be easily realized using representations in projective coordinates and involves roughly $3*1$ finite field multiplications, thus allowing switching between alternative representations at relatively low incremental cost compared to that of elliptic curve scalar multiplications (provided the isogeny has low degree l). Note, however, that this does require storage of the polynomial coefficients of the isogeny and dual isogeny involved. This illustrates that low-degree isogenies are to be preferred, since an l -isogeny (usually) requires storing roughly $6*1$ elements of $GF(q)$. While there are many isogenies, we therefore only consider those with the desired property with lowest possible degree.

Appendix G. Further Cousins of Curve25519

This section introduces some further curves related to Curve25519 and explains their relationships.

G.1. Further Alternative Representations

The Weierstrass curve Wei25519 is isomorphic to the Weierstrass curve Wei25519.2 defined over $GF(p)$, with as base point the pair $(G2X, G2Y)$, and isogenous to the Weierstrass curve Wei25519.-3 defined over $GF(p)$, with as base point the pair $(G3X, G3Y)$, where parameters are as specified in Appendix G.3 and where the related mappings are as specified in Appendix G.2.

G.2. Further Switching

Each affine point (X, Y) of Wei25519 corresponds to the point $(X', Y') := (X*s^2, Y*s^3)$ of Wei25519.2, where s is the element of $GF(p)$ defined by

```
s  20343593038935618591794247374137143598394058341193943326473831977
   39407761440
```

```
(=0x047f6814 6d568b44 7e4552ea a5ed633d 02d62964 a2b0a120
5e7941e9 375de020),
```

while the point at infinity of Wei25519 corresponds to the point at infinity of Wei25519.2. (Here, we used the mapping of Appendix F.3.) Under this mapping, the base point (GX, GY) of Wei25519 corresponds to the base point $(G2X, G2Y)$ of Wei25519.2. The inverse mapping maps the affine point (X', Y') of Wei25519.2 to $(X, Y) := (X'/s^2, Y'/s^3)$ of Wei25519, while mapping the point at infinity O of Wei25519.2 to the point at infinity O of Wei25519. Note that this mapping (and its inverse) involves a modular multiplication of both coordinates with fixed constants s^2 and s^3 (respectively, $1/s^2$ and $1/s^3$), which can be precomputed.

Each affine point (X, Y) of Wei25519 corresponds to the point $(X', Y') := (X1*t^2, Y1*t^3)$ of Wei25519.-3, where $(X1, Y1) = (u(X)/w(X)^2, Y*v(X)/w(X)^3)$, where u , v , and w are the polynomials with coefficients in $GF(p)$ as defined in Appendix G.4.1 and where t is the element of $GF(p)$ defined by

```
t  35728133398289175649586938605660542688691615699169662967154525084
   644181596229
```

```
(=0x4efd6829 88ff8526 e189f712 5999550c e9ef729b ed1a7015
73b1bab8 8bfcd845),
```

while the point at infinity of Wei25519 corresponds to the point at infinity of Wei25519.-3. (Here, we used the isogenous mapping of Appendix F.4.) Under this isogenous mapping, the base point (GX,GY) of Wei25519 corresponds to the base point (G3X,G3Y) of Wei25519.-3. The dual isogeny maps the affine point (X',Y') of Wei25519.-3 to the affine point $(X,Y):=(u'(X1)/w'(X1)^2,Y1*v'(X1)/w'(X1)^3)$ of Wei25519, where $(X1,Y1)=(X'/t^2,Y'/t^3)$ and where u' , v' , and w' are the polynomials with coefficients in GF(p) as defined in Appendix G.4.2, while mapping the point at infinity O of Wei25519.-3 to the point at infinity O of Wei25519. Under this dual isogenous mapping, the base point (G3X, G3Y) of Wei25519.-3 corresponds to a multiple of the base point (GX, GY) of Wei25519, where this multiple is $l=47$ (the degree of the isogeny; see the description in Appendix F.4). Note that this isogenous map (and its dual) primarily involves the evaluation of three fixed polynomials involving the x-coordinate, which takes roughly 140 modular multiplications (or less than 5-10% relative incremental cost compared to the cost of an elliptic curve scalar multiplication).

G.3. Further Domain Parameters

The parameters of the Weierstrass curve with $a=2$ that is isomorphic with Wei25519 and the parameters of the Weierstrass curve with $a=-3$ that is isogenous with Wei25519 are as indicated below. Both domain parameter sets can be exploited directly to derive more efficient point addition formulae, should an implementation facilitate this.

G.4. Isogeny Details

The isogeny and dual isogeny are both isogenies with degree $l=47$. Both are specified by a triple of polynomials u , v , and w (resp. u' , v' , and w') of degree 47, 69, and 23, respectively, with coefficients in $\text{GF}(p)$. The coefficients of each of these polynomials are specified in Appendix G.4.1 (for the isogeny) and in Appendix G.4.2 (for the dual isogeny). For each polynomial in variable x , the coefficients are tabulated as the sequence of coefficients of x^0 , x^1 , x^2 , ..., in hexadecimal format.

Appendix H. Point Compression

Point compression allows a shorter representation of affine points of an elliptic curve by exploiting algebraic relationships between the coordinate values based on the defining equation of the curve in question. Point decompression refers to the reverse process, where one tries and recover an affine point from its compressed representation and information on the domain parameters of the curve. Consequently, point compression followed by point decompression is the identity map.

The description below makes use of an auxiliary function (the parity function), which we first define for prime fields $GF(p)$, with p odd, and then extend to all fields $GF(q)$, where q is an odd prime power. We assume each finite field to be unambiguously defined and known from context.

Let y be a nonzero element of $GF(q)$. If $q=p$ is an odd prime number, y and $p-y$ can be uniquely represented as integers in the interval $[1, p-1]$ and have odd sum p . Consequently, one can distinguish y from $-y$ via the parity of this representation, i.e., via $\text{par}(y) := y \pmod{2}$. If $q=p^m$, where p is an odd prime number and where $m > 0$, both y and $-y$ can be uniquely represented as vectors of length m , with coefficients in $GF(p)$ (see Appendix B.2). In this case, the leftmost nonzero coordinate values of y and $-y$ are in the same position and have representations in $[1, p-1]$ with different parity. As a result, one can distinguish y from $-y$ via the parity of the representation of this coordinate value. This extends the definition of the parity function to any odd-size field $GF(q)$, where one defines $\text{par}(0) := 0$. The value of the parity function is commonly called the parity bit.

H.1. Point Compression for Weierstrass Curves

If $P := (X, Y)$ is an affine point of the Weierstrass curve $W_{\{a,b\}}$ defined over the field $GF(q)$, then so is $-P := (X, -Y)$. Since the defining equation $Y^2 = X^3 + aX + b$ has at most two solutions with fixed X -value, one can represent P by its X -coordinate and one bit of information that allows one to distinguish P from $-P$, i.e., one can represent P as the ordered pair $\text{compr}(P) := (X, \text{par}(Y))$. If P is a point of order two, one can uniquely represent P by its X -coordinate alone, since $Y=0$ and has fixed parity. Conversely, given the ordered pair (X, t) , where X is an element of $GF(q)$ and where $t=0$ or $t=1$, and

the domain parameters of the curve $W_{\{a,b\}}$, one can use the defining equation of the curve to try and determine candidate values for the Y-coordinate given X, by solving the quadratic equation $Y^2 := \alpha$, where $\alpha := X^3 + aX + b$. If α is not a square in $GF(q)$, this equation does not have a solution in $GF(q)$ and the ordered pair (X, t) does not correspond to a point of this curve. Otherwise, there are two solutions, viz. $Y = \sqrt{\alpha}$ and $-Y$. If α is a nonzero element of $GF(q)$, one can uniquely recover the Y-coordinate for which $\text{par}(Y) := t$ and, thereby, the point $P := (X, Y)$. This is also the case if $\alpha = 0$ and $t = 0$, in which case $Y = 0$ and the point P has order two. However, if $\alpha = 0$ and $t = 1$, the ordered pair (X, t) does not correspond to the outcome of the point compression function.

NOTE: the procedure above corrects an error in the point decompression procedure for Weierstrass curves defined over the prime field $GF(p)$ of [SEC1], which erroneously converts a purported compressed point for which $\alpha = 0$ and $t = 1$ (in the notation above), to the ordered pair $(0, p)$.

We extend the definition of the point compression function to all points of the curve $W_{\{a,b\}}$, by associating the (non-affine) point at infinity O with any ordered pair $\text{compr}(O) := (X, 0)$, where X is any element of $GF(q)$ for which $\alpha := X^3 + aX + b$ is not a square in $GF(q)$, and recover this point accordingly. In this case, the point at infinity O can be represented by any ordered pair $(X, 0)$ of elements of $GF(q)$ for which $X^3 + aX + b$ is not a square in $GF(q)$. Note that this ordered pair does not satisfy the defining equation of the curve in question. An application may fix a specific suitable value of X or choose multiple such values and use this to encode additional information. Further details are out of scope.

H.2. Point Compression for Montgomery Curves

If $P := (u, v)$ is an affine point of the Montgomery curve $M_{\{A,B\}}$ defined over the field $GF(q)$, then so is $-P := (u, -v)$. Since the defining equation $Bv^2 = u^3 + Au^2 + u$ has at most two solutions with fixed u -value, one can represent P by its u -coordinate and one bit of information that allows one to distinguish P from $-P$, i.e., one can represent P as the ordered pair $\text{compr}(P) := (u, \text{par}(v))$. If P is a point of order two, one can uniquely represent P by its u -coordinate alone, since $v = 0$ and has fixed parity. Conversely, given the ordered pair (u, t) , where u is an element of $GF(q)$ and where $t = 0$ or $t = 1$, and the domain parameters of the curve $M_{\{A,B\}}$, one can use the defining equation of the curve to try and determine candidate values for the v -coordinate given u , by solving the quadratic equation $v^2 := \alpha$, where $\alpha := (u^3 + Au^2 + u)/B$. If α is not a square in $GF(q)$, this equation does not have a solution in $GF(q)$ and the ordered pair (u, t) does not correspond to a point of this curve. Otherwise,

there are two solutions, viz. $v=\sqrt{\alpha}$ and $-v$. If α is a nonzero element of $\text{GF}(q)$, one can uniquely recover the v -coordinate for which $\text{par}(v):=t$ and, thereby, the affine point $P:=(u, v)$. This is also the case if $\alpha=0$ and $t=0$, in which case $v=0$ and the point P has order two. However, if $\alpha=0$ and $t=1$, the ordered pair (u, t) does not correspond to the outcome of the point compression function.

We extend the definition of the point compression function to all points of the curve $M_{\{A,B\}}$, by associating the (non-affine) point at infinity O with the ordered pair $\text{compr}(O):=(0,1)$ and recover this point accordingly. (Note that this corresponds to the case $\alpha=0$ and $t=1$ above.) The point at infinity O can be represented by the ordered pair $(0, 1)$ of elements of $\text{GF}(q)$. Note that this ordered pair does not satisfy the defining equation of the curve in question.

H.3. Point Compression for Twisted Edwards Curves

If $P:=(x, y)$ is an affine point of the twisted Edwards curve $E_{\{a,d\}}$ defined over the field $\text{GF}(q)$, then so is $-P:=(-x, y)$. Since the defining equation $a*x^2+y^2=1+d*x^2*y^2$ has at most two solutions with fixed y -value, one can represent P by its y -coordinate and one bit of information that allows one to distinguish P from $-P$, i.e., one can represent P as the ordered pair $\text{compr}(P):=(\text{par}(x), y)$. If P is a point of order one or two, one can uniquely represent P by its y -coordinate alone, since $x=0$ and has fixed parity. Conversely, given the ordered pair (t, y) , where y is an element of $\text{GF}(q)$ and where $t=0$ or $t=1$, and the domain parameters of the curve $E_{\{a,d\}}$, one can use the defining equation of the curve to try and determine candidate values for the x -coordinate given y , by solving the quadratic equation $x^2:=\alpha$, where $\alpha:=(1-y^2)/(a-d*y^2)$. (Here, observe that the denominator is nonzero for any point of $E_{\{a,d\}}$.) If α is not a square in $\text{GF}(q)$, this equation does not have a solution in $\text{GF}(q)$ and the ordered pair (t, y) does not correspond to a point of this curve. Otherwise, there are two solutions, viz. $x=\sqrt{\alpha}$ and $-x$. If α is a nonzero element of $\text{GF}(q)$, one can uniquely recover the x -coordinate for which $\text{par}(x):=t$ and, thereby, the affine point $P:=(x, y)$. This is also the case if $\alpha=0$ and $t=0$, in which case $x=0$ and the point P has order one or two. However, if $\alpha=0$ and $t=1$, the ordered pair (t, y) does not correspond to the outcome of the point compression function.

Note that the point compression function is defined for all points of the twisted Edwards curve $E_{\{a,d\}}$. Here, the identity element $O:=(0,1)$ is associated with the compressed point $\text{compr}(O):=(0,1)$. (Note that this corresponds to the case $\alpha=0$ and $t=0$ above.)

We extend the definition of the compression function further, to also include a special marker element 'btm', by associating this marker element with the ordered pair $\text{compr}(\text{btm}) := (1,1)$ and recover this marker element accordingly. (Note that this corresponds to the case $\alpha=0$ and $t=1$ above.) The marker element 'btm' can be represented by the ordered pair $(1,1)$ of elements of $\text{GF}(q)$. Note that this ordered pair does not satisfy the defining equation of the curve in question.

Appendix I. Data Conversions

This section introduces various data conversion routines that are useful when representing integers, finite field elements, and curve points as binary or octet strings.

I.1. Strings and String Operations

The string over some alphabet S consisting of the symbols $x_{\{l-1\}}$, $x_{\{l-2\}}$, ..., x_1 , x_0 (each in S), in this order, is denoted by $\text{str}(x_{\{l-1\}}, x_{\{l-2\}}, \dots, x_1, x_0)$. The length of this string (over S) is the number of symbols it contains (here: l). The empty string is the (unique) string of length $l=0$.

The right-concatenation of two strings X and Y (defined over the same alphabet) is the string Z consisting of the symbols of X (in the same order) followed by the symbols of Y (in the same order). The length of the resulting string Z is the sum of the lengths of X and Y . This string operation is denoted by $Z := X || Y$. The string X is called a prefix of Z ; the string Y a postfix. The t -prefix of a string Z of length l is its unique prefix X of length t ; the t -postfix its unique postfix Y of length t (where in both cases t is an integer in the interval $[0, l]$). One can define these notions as well if t is outside the interval $[0, l]$ by stipulating that a t -prefix or t -postfix is the empty string if t is negative and that it is the entire string Z if t is larger than l . Sometimes, a t -prefix of a string Z is denoted by $\text{trunc-left}(Z, t)$; a t -postfix by $\text{trunc-right}(Z, t)$. A string X is called a substring of Z if it is a prefix of some postfix of Z . The string resulting from prepending the string Y with X is the string $X || Y$.

An octet (or byte) is an integer in the interval $[0, 256)$. An octet string is a string, where the alphabet is the set of all octets. A binary string (or bit string, for short) is a string, where the alphabet is the set $\{0, 1\}$ of binary digits. Note that the length of a string is defined in terms of the underlying alphabet, as are the operations in the previous paragraph.

I.2. Conversion between Bit Strings and Integers (BS2I, I2BS)

There is a 1-1 correspondence between bit strings of length l and integers in the interval $[0, 2^l)$, where the bit string $X := \text{str}(x_{\{l-1\}}, x_{\{l-2\}}, \dots, x_1, x_0)$ corresponds to the integer $x := x_{\{l-1\}} * 2^{\{l-1\}} + x_{\{l-2\}} * 2^{\{l-2\}} + \dots + x_1 * 2 + x_0 * 1$. (If $l=0$, the empty bit string corresponds to the integer zero.) Note that while the mapping from bit strings to integers is uniquely defined, the inverse mapping from integers to bit strings is not, since any non-negative integer smaller than 2^t can be represented as a bit string of length at least t (due to leading zero coefficients in base 2 representation). The latter representation is called tight if the bit string representation has minimal length (the so-called bit-length of the integer in question). This defines the mapping BS2I from bit strings to integers and the mapping I2BS(x, l) from non-negative integers smaller than 2^l to bit strings of length l .

I.3. Conversion between Octet Strings and Integers (OS2I, I2OS)

There is a 1-1 correspondence between octet strings of length l and integers in the interval $[0, 256^l)$, where the octet string $X := \text{str}(X_{\{l-1\}}, X_{\{l-2\}}, \dots, X_1, X_0)$ corresponds to the integer $x := X_{\{l-1\}} * 256^{\{l-1\}} + X_{\{l-2\}} * 256^{\{l-2\}} + \dots + X_1 * 256 + X_0 * 1$. (If $l=0$, the empty string corresponds to the integer zero.) Note that while the mapping from octet strings to integers is uniquely defined, the inverse mapping from integers to octet strings is not, since any non-negative integer smaller than 256^t can be represented as an octet string of length at least t (due to leading zero coefficients in base 256 representation). The latter representation is called tight if the octet string representation has minimal length (the so-called byte-length of the integer in question). This defines the mapping OS2I from octet strings to integers and the mapping I2OS(x, l) from non-negative integers smaller than 256^l to octet strings of length l .

I.4. Conversion between Octet Strings and Bit Strings (OS2BS, BS2OS)

There is a 1-1 correspondence between octet strings of length l and bit strings of length $8 * l$, where the octet string $X := \text{str}(X_{\{l-1\}}, X_{\{l-2\}}, \dots, X_1, X_0)$ corresponds to the right-concatenation of the 8-bit strings $x_{\{l-1\}}, x_{\{l-2\}}, \dots, x_1, x_0$, where each octet X_i corresponds to the 8-bit string x_i according to the mapping of Appendix I.2 above. Note that the mapping from octet strings to bit strings is uniquely defined and so is the inverse mapping from bit strings to octet strings, if one prepends each bit string with the smallest number of 0 bits so as to result in a bit string of length divisible by eight (i.e., one uses pre-padding). This defines the mapping OS2BS from octet strings to bit strings and the corresponding

mapping BS2OS from bit strings to octet strings. When we refer to a specific bit position in an octet string, this indicates the corresponding position, when this octet string is viewed as a bit string using the OS2BS mapping above.

I.5. Conversion between Field Elements and Octet Strings (FE2OS, OS2FE)

There is a 1-1 correspondence between elements of the fixed finite field $GF(q)$, where $q:=p^m$, where p is a prime number and where $m>0$, and vectors of length m , with coefficients in $GF(p)$, where each element x of $GF(q)$ is a vector $(x_{\{m-1\}}, x_{\{m-2\}}, \dots, x_1, x_0)$ according to the conventions of Appendix B.2. In this case, this field element can be uniquely represented by the right-concatenation of the octet strings $X_{\{m-1\}}, X_{\{m-2\}}, \dots, X_1, X_0$, where each octet string X_i corresponds to the integer x_i in the interval $[0,p-1]$ according to the mapping of Appendix I.3 above. Note that both the mapping from field elements to octet strings and the inverse mapping from octet strings to field elements are only uniquely defined if each octet string X_i has the same fixed size (e.g., the smallest integer l so that $256^l \geq p$) and if all integers are reduced modulo p . If so, the latter representation is called tight if l is minimal so that $256^l \geq p$. This defines the mapping $FE2OS(x,l)$ from field elements to octet strings and the mapping $OS2FE(X,l)$ from octet strings to field elements, where the underlying field is implicit and assumed to be known from context. In this case, the octet string has length $l*m$. (Observe that with tight representations, the parameter l is uniquely defined by the characteristic p of the field $GF(q)$ in question.) The $OS2FE(X,l)$ mapping is called strict if it operates as the $OS2FE(X,l)$ function, except that it fails whenever it would require at least one modular reduction. Notice that the tight $FE2OS$ mapping followed by the strict $OS2FE$ mapping is the identity map (and, hence, $OS2FE$ never fails in this case).

I.6. Conversion between Elements of $Z \bmod n$ and Octet Strings ($ZnE2OS$, $OS2ZnE$)

There is a 1-1 correspondence between elements of the set Z_n of integers modulo n and integers in the interval $[0,n)$, where each element x of Z_n is uniquely represented by the integer $x \bmod n$. In this case, $x \bmod n$ can be uniquely represented by the octet string X according to the mapping of Appendix I.3 above. Note that both the mapping from elements of Z_n to octet strings and the inverse mapping from octet strings to elements of Z_n are only uniquely defined if the octet string has a fixed size (e.g., the smallest integer l so that $256^l \geq n$) and if all integers are first reduced modulo n . If so, the latter representation is called tight if l is minimal so that $256^l \geq n$. This defines the mapping $ZnE2OS(x,l)$ from elements of

Z_n to octet strings and the mapping $OS2ZnE(X,l)$ from octet strings to elements of Z_n , where the underlying modulus n is implicit and assumed to be known from context. In this case, the octet string has length l . (Observe that with tight representations, the parameter l is uniquely defined by the parameter n in question.) The $OS2ZnE(X,l)$ mapping is called strict if it operates as the $OS2ZnE(X,l)$ function, except that it fails whenever it would require at least one modular reduction. Notice that the tight $ZnE2OS$ mapping followed by the strict $OS2ZnE$ mapping is the identity map (and, hence, $ZnE2OS$ never fails in this case).

Note that if n is a prime number p , the conversions $ZnE2OS$ and $FE2OS$ are consistent, as are $OS2ZnE$ and $OS2FE$. This is, however, no longer the case if n is a strict prime power.

The conversion rules for composite (i.e., non-prime) n values may be useful, e.g., when encoding RSA parameters (or elements of any other non-prime size set Z_n , for that matter).

I.7. Ordering Conventions

One can consider various representation functions, depending on bit-ordering and octet-ordering conventions.

The description below makes use of an auxiliary function (the reversion function), where the reverse of the string $X := \text{str}(x_{\{l-1\}}, x_{\{l-2\}}, \dots, x_1, x_0)$ is defined to be the string $X' := \text{rev}(X) := \text{str}(x_0, x_1, \dots, x_{\{l-2\}}, x_{\{l-1\}})$. Below, we use this reversion function with binary and octet strings.

We now describe representations in most-significant-bit first (msb) or least-significant-bit first (lsb) order and those in most-significant-byte first (MSB) or least-significant-byte first (LSB) order.

One distinguishes the following octet-string representations of integers and field elements:

1. MSB, msb: represent field elements and integers as above, yielding the octet string $\text{str}(X_{\{l-1\}}, X_{\{l-2\}}, \dots, X_1, X_0)$.
2. MSB, lsb: reverse the bit-order of each octet, viewed as 8-bit string, yielding the octet string $\text{str}(\text{rev}(X_{\{l-1\}}), \text{rev}(X_{\{l-2\}}), \dots, \text{rev}(X_1), \text{rev}(X_0))$.
3. LSB, lsb: reverse the octet string and bit-order of each octet, yielding the octet string $\text{str}(\text{rev}(X_{\{0\}}), \text{rev}(X_{\{1\}}), \dots, \text{rev}(X_{\{l-2\}}), \text{rev}(X_{\{l-1\}}))$.

4. LSB, msb: reverse the octet string, yielding the octet string $\text{str}(X_{\{0\}}, X_{\{1\}}, \dots, X_{\{1-2\}}, X_{\{1-1\}})$.

Thus, the 2-octet string "07e3" represents the integer 2019 (=0x07e3) in MSB/msb order, the integer 57,543 (0xe0c7) in MSB/lbs order, the integer 51,168 (0xc7e0) in LSB/lbs order, and the integer 58,119 (=0xe307) in LSB/msb order.

Note that, with the above data conversions, there is still some ambiguity as to how to represent an integer or a field element as a bit string or octet string (due to leading zeros). However, tight representations (as defined above) are non-ambiguous. (Note, in particular, that tightness implies that elements of $\text{GF}(q)$ are always uniquely represented.)

I.8. Conversion Between Curve Points and Octet Strings

For each of the curve models we consider, each affine point is an ordered pair (X, Y) whose coordinates are elements of a finite field $\text{GF}(q)$ and that satisfy the defining equation for the curve in question. Each compressed point is an ordered pair (X, t) (for Weierstrass curves and Montgomery curves) or (t, X) (for twisted Edwards curves) where X is an element of $\text{GF}(q)$ and where t is an element of $\{0,1\}$ (see Appendix H).

The affine point (X, Y) is represented by the ordered pair whose coordinates are the octet string representations of the elements X and Y of $\text{GF}(q)$, respectively, using the tight FE2OS mapping of Appendix I.5. Note that, since we use a tight representation, this results in a pair of octet strings (each of length $l*m$), where the parameters l and m are uniquely defined by the field $\text{GF}(q)$ in question. The inverse mapping results by converting the first and second coordinate of this pair (each an octet string of length $l*m$) to, respectively, the elements X and Y of $\text{GF}(q)$ via the strict OS2FE mapping of Appendix I.5. Note that if it is not a priori known whether the input to this inverse mapping actually represents an affine curve point, one should check that this is indeed an ordered pair of octet strings (each of length $l*m$) and that the output (X, Y) -- if defined -- is indeed an affine point of the curve in question, where this mapping fails if either condition is not satisfied.

The compressed point (X, t) or (t, X) is represented by the ordered pair whose coordinates are the octet string representations of the parity bit t in $\{0,1\}$ and the element X of $\text{GF}(q)$, respectively, using the tight FE2OS mapping of Appendix I.5. Note that, since we use tight representations, this results in an ordered pair of octet strings (of length l and $l*m$, respectively), where the parameters l and m are uniquely defined by the field $\text{GF}(q)$ in question. The

inverse mapping results by converting the first and second coordinate of this pair (each an octet string, of length l and $l*m$, respectively) to, respectively, the element t of $\{0,1\}$ and the element X of $GF(q)$ via the strict OS2FE mapping of Appendix I.5, and representing this as the compressed point (X, t) or (t, X) according to the curve model in question. Note that if it is not a priori known whether the input to this inverse mapping actually represents a compressed curve point, one should check that this is indeed an ordered pair of octet strings (of length l and $l*m$, respectively) and that the output (X, t) or (t, X) -- if defined -- is indeed a compressed point of the curve in question, using the point decompression process for this curve (see Appendix H), where this mapping fails if either condition is not satisfied.

NOTE 1: The representations of affine and compressed points above are as ordered pairs of octet strings. In practice, one often represents these as octet strings instead, via right-concatenation of its coordinates (in left-to-right order). Since each coordinate has known length, this operation is reversible. When appropriate, we refer to the latter as the octet (rather than the pair) representation of a point.

NOTE 2: The octet representation of compressed points above identifies the parity bit t of the curve point in question via the 1-octet representations of the integers 0 and 1. Obviously, other 1-1 mappings are also possible. As an example, with [SEC1], the parity bit t is represented by $0x02$ or $0x03$ depending on whether $t=0$ or $t=1$, respectively. The same [SEC1] specification represents affine points as above (as octet string), but prepends this with the 1-octet prefix $0x04$, and represents the identity element of the curve as the 1-octet string $0x00$. This variable-size point representation has the property that its 1-octet prefix identifies whether it encodes an affine curve point, a compressed point (including parity bit), or the identity element, while the remainder of this representation uniquely determines the curve point's value. While the description in [SEC1] only applies to Weierstrass curves, the description above applies to each of the curve models we consider (i.e., these apply to Montgomery curves and twisted Edwards curves as well) and also applies to curves defined over extension fields. Collectively, we simply refer to this as the "SEC1" point representation.

Note that elements of a prime field $GF(p)$, where p is a 255-bit prime number, have a tight representation as a 32-octet string, where a fixed bit position is always set to zero. (This is the leftmost bit position of this octet string if one follows the MSB/msb representation conventions.) This allows the parity bit of a compressed point (see Appendix H) to be encoded in this bit position

and, thereby, allows a compressed point and an element of $GF(p)$ to be represented by an octet string of the same length. This is called the "squeezed" point representation. (We will use this squeezed representation in Appendix J.) Obviously, other representations (e.g., those of elements of Z_n) may also have fixed bit values in certain positions, which can be used to squeeze-in additional information. Further details are out of scope.

Notice that elements of a prime field $GF(p)$, where p is a prime number with bit-length m divisible by eight, have a tight representation as an $(m/8)$ -octet string, but do not have a bit position that is always set to zero. Thus, in this case, one cannot represent a compressed point as an octet string of the same length as an element of $GF(p)$. However, one can still encode this as an octet string of length $(m/8)+1$ (see Note 1 above). If one uses right-concatenation as in Note 1, but (for historical reasons) represents the parity bit t of the compressed point in question by $0x00$ or $0x80$ depending on whether $t=0$ or $t=1$, respectively, this is again called the "squeezed" representation (despite this being somewhat a misnomer, since each point is now represented as an octet string that is one octet longer than the tight representation of elements of $GF(p)$). Notice that this representation corresponds to the compressed point representation of Appendix I.8 as octet string, but with the bit-ordering in the 1-octet representation of t reversed. (Note that this puts the parity bit t in the leftmost bit position of the octet string if one follows the MSB/msb representation conventions.) We will use this squeezed representation in Appendix O.

Appendix J. Representation Examples Curve25519 Family Members

We present some examples of computations using the curves introduced in Appendix E and Appendix G of this document. In each case, we indicate the values of P , $k*P$, and $(k+1)*P$, where P is a fixed multiple (here: 2019) of the base point of the curve in question and where the private key k is the integer

```
k  45467544759954639344191351164156560595299236761702065033670739677
   691372543056

   c08d5abd 15e29c50).
```

In the examples below, each curve point is represented using the "squeezed" point representation (see Appendix I.8), whereby each point is represented as a 32-octet string, where the ordering convention (see Appendix I.7) depends on the underlying curve model in question. Here, points of a Weierstrass curve are represented in tight MSB/msb-order, points of a Montgomery curve in tight LSB/msb-

order, and points of a twisted Edwards curve in tight LSB/lsw-order. For points that are a public key, the corresponding private keys are represented as 32-octet strings, using the same (tight) ordering conventions as with the public keys. For affine points, we also give the tight representation of each of its coordinates, using the same ordering conventions as used with the squeezed point representation. For further details, see the examples themselves.

J.1. Example with Curve25519

$P_m=(u, v)$, $k*P_m=(u_1, v_1)$, and $(k+1)*P_m=(u_2, v_2)$ with Curve25519:

```

```

As suggested in Appendix C.2, the v -coordinate of $k*P_m$ can be indirectly computed from the u -coordinates of P_m , $k*P_m$, and $(k+1)*P_m$, and the v -coordinate of P_m , which allows computation of the entire point $k*P_m$ (and not just its u -coordinate) if $k*P_m$ is computed using the Montgomery ladder (as, e.g., [RFC7748] recommends), since that algorithm computes both u_1 and u_2 and the v -coordinate of the point P_m may be available from context.

The representation of k and the compressed representations of P_m and $k*P_m$ in tight LSB/msb-order are given by

```
repr(k)      0x509ce215 bd5a8dc0 c3328c77 5dc6f59c 4d4915f9 e4bf5d0d
             c2e583cd e6b78564

repr(Pm)     0x4632f1b7 6724977f 3c8575aa 600129ea 1c93bf9a 2c143447
             74d535df 66753b75;

             d6d6bdf0 be94f15c,
```

where the leftmost bit of the rightmost octet indicates the parity of the v -coordinate of the point of Curve25519 in question (which, in this case, are both zero, since v and v_1 are even). See Appendix H.2 and Appendix I for further detail on (squeezed) point compression.

The scalar representation and (squeezed) point representation illustrated above are consistent with the representations specified in [RFC7748], except that in [RFC7748] only an affine point's u -coordinate is represented (i.e., the v -coordinate of any point is always implicitly assumed to have an even value) and that the representation of the point at infinity is not specified. Another difference is that [RFC7748] allows non-unique representations of some elements of $GF(p)$, whereas our representation conventions do not (since tight).

A randomized representation (t_1, t_2) of the point $k*P_m$ in tight LSB/msb order is given by

```
t1          409531317901122685707535715924445398426503483189854716584

The representation of k and the compressed representations of Pe and $k*Pe$ in tight LSB/lsw-order are given by

repr(k) =0x0a3947a8 bd5ab103 c34c31ee ba63af39 b292a89f 27fdbab0
43a7c1b3 67eda126;

repr(Pe) =0x0bf0c5cd a3a0e069 183c8559 40dc816a e3fa8e6c 4b286bc4
71b72ee6 e79f1a1e;

repr($k*Pe$) =0x3a293d01 e4110a06 b9c2d02a bff7abac 40a918df 69bbfa3d
f5b5da19 923d6da7,

where the rightmost bit of the rightmost octet indicates the parity of the x -coordinate of the point of Edwards25519 in question (which, in this case, are zero and one, respectively, since x is even and x_1 is odd). See Appendix H.3 and Appendix I for further detail on (squeezed) point compression.

The scalar representation and (squeezed) point representation illustrated above are fully consistent with the representations specified in [RFC8032]. Note that, contrary to [RFC7748], [RFC8032] requires unique representations of all elements of $GF(p)$.

A randomized representation (t_1, t_2) of the point $k*Pe$ in tight LSB/lsw order is given by

t1 577913017083163641949634219017190182170288776648725395935

fbc17f7f 7fda8518).

The representation of k and the compressed representations of P_w and $k*P_w$ in tight MSB/msb-order are given by

repr(k) =0x6485b7e6 cd83e5c2 0d5dbfe4 f915494d 9cf5c65d 778c32c3
c08d5abd 15e29c50;

repr(P_w) =0x1fe62011 89e0801e f1debed7 456a3dc7 94d3ac0b 55202fe7
2a41cf12 629e56aa;

repr($k*P_w$) =0x079c3f69 9b688181 69038c35 39c11eb5 96d09f5b 12a242b4
ce660f13 3368c13c,

where the leftmost bit of the leftmost octet indicates the parity of the Y-coordinate of the point of Wei25519 in question (which, in this case, are both zero, since Y and Y_1 are even). See Appendix H.1 and Appendix I for further detail on (squeezed) point compression.

The scalar representation is consistent with the representations specified in [SEC1]; the (squeezed) point representation illustrated above is "new". For completeness, we include a SEC1-consistent representation of the point P_w in affine format and in compressed format below.

The SEC1-compliant affine representation of the point P_w in tight MSB/msb-order is given by

```
aff(Pw)      =0x04 1fe62011 89e0801e fldebed7 456a3dc7 94d3ac0b
              55202fe7 2a41cf12 629e56aa

              75e676ce deee3b3c 12942357 22f1d884 ac06de07 330fb07b
              ae35ca26 df75417e,
```

whereas the SEC1-compliant compressed representation of the point P_w in tight MSB/msb-order is given by

```
compr(Pw)    =0x02 1fe62011 89e0801e fldebed7 456a3dc7 94d3ac0b
              55202fe7 2a41cf12 629e56aa;
```

The SEC1-compliant uncompressed format $\text{aff}(P_w)$ of an affine point P_w corresponds to the right-concatenation of its X- and Y-coordinates, each in tight MSB/msb-order, prepended by the string $0x04$, where the reverse procedure is uniquely defined, since elements of $\text{GF}(p)$ have a unique fixed-size representation. The (squeezed) compressed format $\text{repr}(P_w)$ corresponds to the SEC1-compliant compressed format by extracting the parity bit t from the leftmost bit of the leftmost octet of $\text{repr}(P_w)$, replacing the bit position by the value zero, and prepending the octet string with $0x02$ or $0x03$, depending on whether $t=0$ or $t=1$, respectively, where the reverse procedure is uniquely defined, since $\text{GF}(p)$ is a 255-bit prime field. For further details, see [SEC1]. Note that, due to the bit-length of the prime p , the squeezed compressed format $\text{repr}(P_w)$ is one octet shorter than the SEC1-compliant compressed format $\text{compr}(P_w)$.

A randomized representation (t_1, t_2) of the point $k \cdot P_w$ in tight MSB/msb order is given by

```
t1           446363445988889734093446280484122107283059206243307955388

```

where this uses the default completed mapping defined in Appendix K.6 and the mapping of Appendix K.4.1 (with the default square root function).

Appendix K. Auxiliary Functions

This section illustrates how one could implement common routines, such as taking square roots and inverses in finite fields, and how to map field elements to curve points and to curve points that avoid outlier points in the small subgroup.

K.1. Square Roots in $GF(q)$

Square roots are easy to compute in $GF(q)$ if $q = 3 \pmod{4}$ (see Appendix K.1.1) or if $q = 5 \pmod{8}$ (see Appendix K.1.2). Details on how to compute square roots for other values of q are out of scope. If square roots are easy to compute in $GF(q)$, then so are these in $GF(q^2)$.

K.1.1. Square Roots in $GF(q)$, where $q = 3 \pmod{4}$

If y is a nonzero element of $GF(q)$ and $z := y^{\{(q-3)/4\}}$, then y is a square in $GF(q)$ only if $y*z^2=1$. If $y*z^2=1$, z is a square root of $1/y$ and $y*z$ is a square root of y in $GF(q)$.

K.1.2. Square Roots in $GF(q)$, where $q = 5 \pmod{8}$

If y is a nonzero element of $GF(q)$ and $z := y^{\{(q-5)/8\}}$, then y is a square in $GF(q)$ only if $y^2*z^4=1$.

- a. If $y*z^2=+1$, z is a square root of $1/y$ and $y*z$ is a square root of y in $GF(q)$;

- b. If $y*z^2=-1$, $i*z$ is a square root of $1/y$ and $i*y*z$ is a square root of y in $GF(q)$.

Here, i is an element of $GF(q)$ for which $i^2=-1$ (e.g., $i:=2^{\{(q-1)/4\}}$). This field element can be precomputed.

K.2. Inversion

If y is an integer and $\gcd(y,n)=1$, one can efficiently compute $1/y \pmod n$ via the extended Euclidean Algorithm (see Section 2.2.5 of [GECC]). One can use this algorithm as well to compute the inverse of a nonzero element y of a prime field $GF(p)$, since $\gcd(y,p)=1$.

The inverse of a nonzero element y of $GF(q)$ can be computed as

$$1/y := y^{\{q-2\}} \text{ (since } y^{\{q-1\}}=1\text{)}.$$

If inverses are easy to compute in $GF(q)$, then so are these in $GF(q^2)$. Further details are out of scope.

The inverses of two nonzero elements y_1 and y_2 of $GF(q)$ can be computed by first computing the inverse z of y_1*y_2 and by subsequently computing $y_2*z:=1/y_1$ and $y_1*z:=1/y_2$.

NOTE 1: This method can be used to compute the inverse of a nonzero element y of $GF(q)$ indirectly, as $\lambda*(\lambda*y)^{\{-1\}}$, where λ is a random nonzero element of $GF(q)$. This yields an inversion routine (commonly called "blinded inversion") where the inversion operation itself does not leak information on y .

NOTE 2: This method can also be used to compute the inverse and a square root, respectively, of two nonzero elements x and y of $GF(q)$ by first computing a square root z of $1/(y*x^2)$ (see Appendix K.1) and by subsequently computing a square root of y as $x*y*z$ and the inverse of x as $x*y*z^2$.

K.3. Mappings to Curve Points

One can map elements of $GF(q)$ that are not a square in $GF(q)$ to points of a Weierstrass curve (see Appendix K.3.1), to points of a Montgomery curve (see Appendix K.3.2), or to points of a twisted Edwards curve (see Appendix K.3.3), under some mild conditions on the domain parameters. Full details on mappings that apply if these conditions are not satisfied are out of scope.

K.3.1. Mapping to Points of Weierstrass Curve

The description below assumes that the domain parameters a and b of the Weierstrass curve $W_{\{a,b\}}$ are nonzero. For ease of exposition, we define $f(z) := z^3 + a*z + b$. (Note that for an affine point (X, Y) of $W_{\{a,b\}}$ one has $Y^2 = f(X)$.)

If t is an element of $GF(q)$ that is not a square in $GF(q)$ and that is unequal to -1 , then the element $X := (-b/a) * (1 + 1/(t + t^2))$ is the unique solution of the equation $f(t*X) = t^3 * f(X)$ and is nonzero.

Consequently, either X or $X' := t*X$ is the x -coordinate of an affine point of $W_{\{a,b\}}$, depending on whether $f(X)$ is a square in $GF(q)$.

- a. If $f(X)$ is a square in $GF(q)$ and $Y := \text{sqrt}(f(X))$, then t is mapped to the point $P(t) := (X, Y)$;
- b. If $f(X)$ is not a square in $GF(q)$ and $Y' := \text{sqrt}(f(X'))$, then t is mapped to the point $P(t) := (X', -Y')$.

Formally, this mapping is not properly defined, since a nonzero square $y := x^2$ in $GF(q)$ has two solutions, viz. x and $-x$; it is properly defined, however, if one designates for each element of $GF(q)$ that is a square in $GF(q)$ precisely one square root as "the" square root of this element. Note that always picking the square root with zero parity (see Appendix H) satisfies this condition (henceforth called the default square root function).

If -1 is not a square in $GF(q)$, this element is mapped to the point at infinity O of $W_{\{a,b\}}$.

The set of points of $W_{\{a,b\}}$ that arises this way has size roughly $3/8$ of the order of the curve and each such point arises as image of one or two t values. Further details are out of scope.

NOTE 1: If -1 is not a square in $GF(q)$, the mapping above yields the point at infinity for $t = -1$. One can modify this mapping, by mapping the element -1 to any suitable point P_0 of $W_{\{a,b\}}$ (e.g., its base point G or any other affine point) and leaving the remainder of the mapping the same. Suitability of such a modification is application-specific. Details are out of scope.

NOTE 2: The description above assumes that the domain parameters a and b of the Weierstrass curve $W_{\{a,b\}}$ are nonzero. If this is not the case, one can often find an isogenous curve $W_{\{a',b'\}}$ for which the domain parameters a' and b' are nonzero. If so, one can map elements of $GF(q)$ that are not a square in $GF(q)$ to points of $W_{\{a,b\}}$ via function composition, where one uses the mapping above to arrive at a point of $W_{\{a',b'\}}$ and where one subsequently uses the dual

isogeny from $W_{\{a',b'\}}$ to $W_{\{a,b\}}$ to arrive at a point of $W_{\{a,b\}}$. As an example, one can show that if a is zero and if $-4*b$ is a cube in $GF(q)$ (such as is the case with, e.g., the "BitCoin" curve secp256k1 [SEC2]), this curve is 3-isogenous to a curve with this property and the strategy above applies (for an example with secp256k1, see Appendix L). Further details are out of scope.

K.3.2. Mapping to Points of Montgomery Curve

The description below assumes that the domain parameter A of the Montgomery curve $M_{\{A,B\}}$ is nonzero. For ease of exposition, we define $f(z) := z^3 + A*z^2 + z$. (Note that for an affine point (u,v) of $M_{\{A,B\}}$ one has $B*v^2 = f(u)$.)

If t is an element of $GF(q)$ that is not a square in $GF(q)$ and that is unequal to -1 , then the element $u := -(1+1/t)/A$ is the unique nonzero solution of the equation $f(t*u) = t^3*f(u)$. Consequently, either u or $u' := t*u$ is the u -coordinate of an affine point of $M_{\{A,B\}}$, depending on whether $f(u)/B$ is a square in $GF(q)$.

- a. If $f(u)/B$ is a square in $GF(q)$ and $v := \text{sqrt}(f(u)/B)$, then t is mapped to the point $P(t) := (u, v)$;
- b. If $f(u)/B$ is not a square in $GF(q)$ and $v' := \text{sqrt}(f(u')/B)$, then t is mapped to the point $P(t) := (u', -v')$.

As before, formally, this mapping is not properly defined, since a nonzero square $y := x^2$ in $GF(q)$ has two solutions, viz. x and $-x$; it is properly defined, however, if one designates for each element of $GF(q)$ that is a square in $GF(q)$ precisely one square root as "the" square root of this element. Note that always picking the square root with zero parity (see Appendix H) satisfies this condition (henceforth called the default square root function).

If -1 is not a square in $GF(q)$, this element is mapped to the point at infinity O of $M_{\{A,B\}}$.

The set of points of $M_{\{A,B\}}$ that arises this way has size roughly $1/2$ of the order of the curve and each such point arises as image of precisely one t value. Further details are out of scope.

NOTE 1: If -1 is not a square in $GF(q)$, the mapping above yields the point at infinity for $t = -1$. One can modify this mapping, by mapping the element -1 to any suitable point P_0 of $M_{\{a,b\}}$ (e.g., its base point G or any other affine point) and leaving the remainder of the mapping the same. Suitability of such a modification is application-specific. Details are out of scope.

NOTE 2: The description above assumes that the domain parameter A of the Montgomery curve $M_{\{A,B\}}$ is nonzero. If this is not the case, the curve is a Weierstrass curve for which the domain parameter b is zero and Note 2 of Appendix K.3.1 applies. If $q = 3 \pmod{4}$, an even simpler approach is possible, where one modifies the construction above and simply takes $u:=t$ and $u':=-t$ (which works, since -1 is not a square in $GF(q)$ and $f(-t)=-f(t)$). In this case, this construction can be extended to all elements t of $GF(q)$ and, if so, yields a 1-1 mapping between $GF(q)$ and all affine curve points.

K.3.3. Mapping to Points of Twisted Edwards Curve

One can map elements of $GF(q)$ that are not a square in $GF(q)$ to points of the twisted Edwards curve $E_{\{a,d\}}$ via function composition, where one uses the mapping of Appendix K.3.1 to arrive at a point of the Weierstrass curve $W_{\{a,b\}}$ and where one subsequently uses the isomorphic mapping between twisted Edwards curves and Weierstrass curves of Appendix D.3 to arrive at a point of $E_{\{a,d\}}$. Another mapping is obtained by function composition, where one instead uses the mapping of Appendix K.3.2 to arrive at a point of the Montgomery curve $M_{\{A,B\}}$ and where one subsequently uses the isomorphic mapping between twisted Edwards curves and Montgomery curves of Appendix D.1 to arrive at a point of $E_{\{a,d\}}$. Obviously, one can use function composition (now using the respective pre-images - if these exist) to realize the pre-images of either mapping.

K.4. Mappings to High-Order Curve Points

Appendix K.3 described how one can map elements of $GF(q)$ that are not a square in $GF(q)$ to points of a Weierstrass curve, to points of a Montgomery curve, or to points of a twisted Edwards curve, under some mild conditions on the domain parameters. Below, we use the mappings of that appendix and the parity function `par(.)` specified in Appendix H to construct mappings to high-order curve points only (i.e., mappings that avoid points in the small subgroup, see Appendix B.1). We consider mappings to high-order points of a Weierstrass curve (see Appendix K.4.1), to high-order points of a Montgomery curve (see Appendix K.4.2), and to high-order points of a twisted Edwards curve (see Appendix K.4.3). As before, full details on mappings that apply if the mild conditions on the domain parameters are not satisfied are out of scope.

K.4.1. Mapping to High-Order Points of Weierstrass Curve

The description below assumes that the domain parameters a and b of the Weierstrass curve $W_{\{a,b\}}$ are nonzero. For ease of exposition, we define $f(z):=z^3+a*z+b$. (Note that for an affine point (X,Y) of $W_{\{a,b\}}$ one has $Y^2=f(X)$.)

If t is an element of $GF(q)$ that is not a square in $GF(q)$ and that is unequal to -1 , the mapping of Appendix K.3.1 yields an affine point $P(t) := (X, Y)$ of $W_{\{a,b\}}$. Let $P_0 := (X_0, Y_0)$ be a fixed affine point of $W_{\{a,b\}}$ for which neither P_0 , $P_0 + P(t)$, nor $P_0 - P(t)$ is in the small subgroup of $W_{\{a,b\}}$. (Note that this implies that P_0 and $P(t)$ are distinct affine points of the curve and that these are not each other's inverse.) For binary digit s , the point $Q(t,s)$ is now defined as follows:

- a. If $\text{par}(Y_0*Y) = s$, then the pair (t,s) is mapped to the point $Q(t,s) := P_0 + P(t)$;
- b. If $\text{par}(Y_0*Y) \neq s$, then the pair (t,s) is mapped to the point $Q(t,s) := P_0 - P(t)$.

Note that this mapping is properly defined as long as the fixed point P_0 (the so-called "curve offset") alluded to above indeed exists. In cases of practical interest that we are aware of, this is indeed the case (see, e.g., Table 1).

If -1 is not a square in $GF(q)$, the pair $(-1,s)$ is mapped to the affine point P_0 of $W_{\{a,b\}}$ (irrespective of the value of s).

The set of points of $W_{\{a,b\}}$ that arises this way has size roughly $3/8$ of the order of the curve and each such point arises as image of up to four values of the pair (t,s) . Further details are out of scope.

From the group law for Weierstrass curves (see Appendix C.1) it follows that one can express the coordinates of $Q(t,s)$, with $t \neq -1$, in terms of the X -coordinates of P_0 and $P(t)$ and the product of their Y -coordinates. (Here, observe that Y_0*Y is a square root of $f(X_0)*f(X)$.) Thus, $Q(t,s)$ can be computed without the need to fully compute $P(t)$.

K.4.2. Mapping to High-Order Points of Montgomery Curve

The description below assumes that the domain parameters A and B of the Montgomery curve $M_{\{A,B\}}$ are nonzero. For ease of exposition, we define $f(z) := z^3 + A*z^2 + z$. (Note that for an affine point (u,v) of $M_{\{A,B\}}$ one has $B*v^2 = f(u)$.)

If t is an element of $GF(q)$ that is not a square in $GF(q)$ and that is unequal to -1 , the mapping of Appendix K.3.2 yields an affine point $P(t) := (u, v)$ of $M_{\{A,B\}}$. Let $P_0 := (u_0, v_0)$ be a fixed affine point of $M_{\{A,B\}}$ for which neither P_0 , $P_0 + P(t)$, nor $P_0 - P(t)$ is in the small subgroup of $M_{\{A,B\}}$. (Note that this implies that P_0 and $P(t)$ are distinct affine points of the curve and that these are not each

other's inverse.) For binary digit s , the point $Q(t,s)$ is now defined as follows:

- a. If $\text{par}(B*v_0*v)=s$, then the pair (t,s) is mapped to the point $Q(t,s):=P_0 + P(t)$;
- b. If $\text{par}(B*v_0*v)\neq s$, then the pair (t,s) is mapped to the point $Q(t,s):=P_0 - P(t)$.

Note that this mapping is properly defined as long as the fixed point P_0 (the so-called "curve offset") alluded to above indeed exists. In cases of practical interest that we are aware of, this is indeed the case (see, e.g., Table 1).

If -1 is not a square in $GF(q)$, the pair $(-1,s)$ is mapped to the affine point P_0 of $M_{\{A,B\}}$ (irrespective of the value of s).

The set of points of $M_{\{A,B\}}$ that arises this way has size roughly $1/2$ of the order of the curve and each such point arises as image of up to two values of the pair (t,s) . Further details are out of scope.

From the group law for Montgomery curves (see Appendix C.2) it follows that one can express the coordinates of $Q(t,s)$, with $t\neq -1$, in terms of the u -coordinates of P_0 and $P(t)$ and the product of their v -coordinates. (Here, observe that $B*v_0*v$ is a square root of $f(u_0)*f(u)$.) Thus, $Q(t,s)$ can be computed without the need to fully compute $P(t)$.

Table 1: Fixed curve offsets for mappings that avoid low-order points, for some curves of practical interest, including listing of fixed non-square elements of their underlying finite fields.

K.4.3. Mapping to High-Order Points of Twisted Edwards Curve

One can map elements of $GF(q)$ that are not a square in $GF(q)$ to points of the twisted Edwards curve $E_{\{a,d\}}$ via function composition, where one uses the mapping of Appendix K.4.1 to arrive at a point of the Weierstrass curve $W_{\{a,b\}}$ that is not in the small subgroup and where one subsequently uses the isomorphic mapping between twisted Edwards curves and Weierstrass curves of Appendix D.3 to arrive at a point of $E_{\{a,d\}}$ with this property. Another mapping is obtained by function composition, where one instead uses the mapping of Appendix K.4.2 to arrive at a point of the Montgomery curve $M_{\{A,B\}}$ that does not have low order and where one subsequently uses the isomorphic mapping between twisted Edwards curves and Montgomery curves of Appendix D.1 to arrive at a point of $E_{\{a,d\}}$ with this property. Obviously, one can use function composition (now using the respective pre-images - if these exist) to realize the pre-images of either mapping.

K.5. Randomized Representation of Curve Points

The mappings of Appendix K.3 allow one to represent a curve point Q as a specific element t of $GF(q)$, provided this point arises as a point in the range of the mapping at hand. For Montgomery curves and twisted Edwards curves, this covers roughly half of the curve points; for Weierstrass curves, roughly $3/8$ of the curve points. One can extend the mappings above, by mapping a pair (t_1, t_2) of inputs to the point $Q := P_2(t_1, t_2) := P(t_1) + P(t_2)$. In this case, each curve point has roughly $q/4$ representations as an ordered pair (t_1, t_2) on average. In fact, one can show that if the input pairs are generated uniformly at random, then the corresponding curve points follow a distribution that is also (statistically indistinguishable from) a uniform distribution, and vice-versa. Here, each pair (t_1, t_2) deterministically yields a curve point, whereas for each curve point Q , a randomized algorithm yields an ordered pair (t_1, t_2) of pre-images of Q , where the expected number of randomized pre-images one has to try is small (four if one uses the mapping of Appendix K.3.1; two if one uses the mapping of Appendix K.3.2). For further details, see Algorithm 1 of [Tibouchi].

Similar properties hold if one uses the mappings of Appendix K.4 (rather than those of Appendix K.3): in this case, the mapping allows one to represent a curve point Q as a specific element (t, s) of $GF(q) \times \{0, 1\}$, provided this point arises as a point in the range of the mapping at hand. For Montgomery curves and twisted Edwards curves, this covers roughly half of the curve points; for Weierstrass curves, roughly $3/8$ of the curve points. One can extend the mappings above, by mapping a pair $((t_1, s_1), (t_2, s_2))$ of inputs to the point $Q := Q_2((t_1, s_1), (t_2, s_2)) := Q(t_1, s_1) - Q(t_2, s_2)$. In this case, each curve point has roughly q representations as an ordered pair $((t_1, s_1), (t_2, s_2))$ on average. In fact, one can show that if the input pairs are generated uniformly at random, then the corresponding curve points follow a distribution that is also (statistically indistinguishable from) a uniform distribution, and vice-versa. Here, each pair $((t_1, s_1), (t_2, s_2))$ deterministically yields a curve point, whereas for each curve point Q , a randomized algorithm yields an ordered pair $((t_1, s_1), (t_2, s_2))$ of pre-images of Q , where the expected number of randomized pre-images one has to try is small (four if one uses the mapping of Appendix K.4.1; two if one uses the mapping of Appendix K.4.2). Further details are out of scope.

NOTE 1: The main difference between the two constructions above is that the first construction uses the mappings to curve points described in Appendix K.3, while the second construction uses the mappings to high-order curve points described in Appendix K.4. Note that $Q_2((t_1, s_1), (t_2, s_2))$ assumes all values $(+/-) P(t_1) (+/-) P(t_2)$

if one considers all possible values for the binary digits s_1 and s_2 . (This, thereby, includes the value $P_2(t_1, t_2)$.)

NOTE 2: The results on the statistical distributions mentioned above still hold in practice if one makes a few localized changes to the constructions. In particular, these are independent of the specific choices for the point P_0 (used with input -1 with the mappings of Appendix K.3, if applicable, respectively, used with the mappings of Appendix K.4) and also still hold if one re-defines the mappings P_2 or Q_2 locally so as to avoid points in the small subgroup.

K.6. Completing the Mappings to Curve Points

The mappings of Appendix K.4 operate on input pairs (t, s) , where t is an element of $GF(q)$ that is not a square in $GF(q)$ and where s is a binary digit from the set $\{0,1\}$. One can use these mappings to produce mappings that operate on input pairs (u, s) , where u is any nonzero element of $GF(q)$, via function composition, where one first maps the pair (u,s) to the pair $(t,s):=(\delta*u^2,s)$, where δ is a fixed element of $GF(q)$ that is not a square in $GF(q)$, and where one subsequently applies any of forementioned mappings to the resulting pair to yield a point of the curve in question. The resulting mapping to high-order curve points can be extended further to one that operates on all elements of $GF(q)\times\{0,1\}$ by mapping each input (u, s) with $u=0$ to any fixed high-order point P_1 of the curve in question. The resulting mapping is uniquely defined after fixing the curve offset P_0 (used with the mappings of Appendix K.4), the high-order point P_1 (used for inputs with $u=0$ above), and the non-square element δ of $GF(q)$ (used for nonzero inputs u above).

For the mappings of Appendix K.3, one can use a similar function composition, where one simply drops the binary digit s and maps 0 to the point at infinity or any other suitable curve point P_1 . As before, the resulting mapping is uniquely defined after fixing the point P_0 (for input -1 with the mappings of Appendix K.3, if applicable), the point P_1 (used for input $u=0$ above), and the non-square element δ of $GF(q)$ (used for nonzero inputs u above). Further details are out of scope.

Similarly, one can use the completed mappings above to map a pair $((u_1,s_1), (u_2,s_2))$ of elements of $GF(q)\times\{0,1\}$ to a point of a curve, via function composition, where, in the first case, one first maps the pair $((u_1,s_1),(u_2,s_2))$ to the pair $((t_1,s_1), (t_2,s_2)):=((\delta*u_1^2, s_1), (\delta*u_2^2, s_2))$ and subsequently computes $Q_2\text{compl}((t_1,s_1), (t_2,s_2)):=Q\text{compl}(t_1,s_1) - Q\text{compl}(t_2,s_2)$, where $Q\text{compl}(t,s):=Q(t,s)$ if t is nonzero and where $Q\text{compl}(0,s):=P_0$ otherwise (irrespective of the value of s). In the second case, one first maps the pair (u_1, u_2) to the pair $(t_1, t_2):=(\delta*u_1^2,$

$\delta \cdot u_2^2$) and subsequently computes $P2_{\text{compl}}(t_1, t_2) := P_{\text{compl}}(t_1) + P_{\text{compl}}(t_2)$, where $P_{\text{compl}}(t) := P(t)$ if t is nonzero and where $P_{\text{compl}}(0) := P_1$ otherwise. In either case, again, the resulting mapping is uniquely defined after fixing the points P_0 and P_1 and the non-square element δ of $GF(q)$.

NOTE 1: Each of the above mappings is fully and unambiguously defined by the triple (P_0, P_1, δ) . One can locally change this mapping so as to avoid points in the small subgroup, should these otherwise occur, e.g., by setting any such re-defined image to any fixed high-order point P_2 of the curve in question. In this case, the corresponding mapping is uniquely defined by the quadruple (P_0, P_1, P_2, δ) and -- in practice -- has the same statistical distribution properties as the original mapping (see NOTE 2 of Appendix K.5). For each curve in Table 1, these completed mappings are uniquely defined by the mentioned fixed curve offset P_0 and non-square element δ of $GF(q)$, if one defines $P_2 := P_1 := P_0$ (henceforth called the default completed mappings).

NOTE 2: For elliptic curves defined over prime fields (i.e., $q=p$) one can relax the completed mappings above and show that the statistical properties for randomized representations still hold if u_1 is a random element of a sufficiently large interval in $GF(p)$ and if u_2 is a random element of a sufficiently large subset of $GF(p)$ (see, e.g., [Tibouchi-clean-cut]). This allows generating u_1 and u_2 , e.g., each as random bit strings of length $m-1$, where m is the bit-length of p , thereby allowing the pair (u_1, u_2) -- a random $(2 \cdot m - 2)$ -bit string -- to be used unaltered in this construction, without the need to carry out a reduction modulo p first. Table 2 illustrates how this can be used to realize randomized representations and completed mappings for each curve in Table 1, where these randomized bit strings have the same byte-length as the (tight) representation of affine curve points. For each curve in Table 2, we refer to this version of the default completed mapping as being the "clean-cut" default completed mapping. Further details are out of scope of this document.

Appendix L. Curve secp256k1 and Friend

This section illustrates how isogenies can be used to yield curves with specific properties (here, illustrated for the "BitCoin" curve secp256k1).

L.1. Curve Definition and Alternative Representation

The elliptic curve secp256k1 is the Weierstrass curve $W_{\{a,b\}}$ defined over the prime field $GF(p)$, with $p:=2^{256}-2^{32}-2^9-2^8-2^7-2^6-2^4-1$, where $a:=0$ and $b:=7$. This curve has order $h*n$, where $h=1$ and where n is a prime number. For this curve, domain parameter a is zero, whereas b is not. The quadratic twist of this curve has order $h1*n1$, where $h1$ is a 37-bit integer and where $n1$ is a prime number. For this curve, the base point is the point (GX, GY) .

L.4. Isogeny Details

The isogeny and dual isogeny are both isogenies with degree $l=3$. Both are specified by a triple of polynomials u , v , and w (resp. u' , v' , and w') of degree 3, 3, and 1, respectively, with coefficients in $\text{GF}(p)$. The coefficients of each of these polynomials are specified in Appendix L.4.1 (for the isogeny) and in Appendix L.4.2 (for the dual isogeny). For each polynomial in variable x , the coefficients are tabulated as the sequence of coefficients of x^0 , x^1 , x^2 , ..., in hexadecimal format.

Appendix M. Curve448 and Cousins

This section introduces curves related to Curve448 and explains their relationships.

M.1. Curve Definition and Alternative Representations

The elliptic curve Curve448 is the Montgomery curve $M_{\{A,B\}}$ defined over the prime field $GF(p)$, with $p:=2^{\{448\}}-2^{\{224\}}-1$, where $A:=156326$ and $B:=1$. This curve has order $h*n$, where $h=4$ and where n is a prime number. For this curve, A^2-4 is not a square in $GF(p)$, whereas $A-2$ is. The quadratic twist of this curve has order $h1*n1$, where $h1=4$ and where $n1$ is a prime number. For this curve, the base point is the point (Gu, Gv) , where $Gu=5$ and where Gv is an even integer in the interval $[0, p-1]$.

This curve has the same group structure as (is "isomorphic" to) the twisted Edwards curve $E_{\{a,d\}}$ defined over $GF(p)$, with as base point the point (Gx, Gy) , where parameters are as specified in Appendix M.3. This curve is denoted as Ed448. For this curve, the parameter a is a square in $GF(p)$, whereas d is not, so the group laws of Appendix C.3 apply.

The curve is also isomorphic to the elliptic curve $W_{\{a,b\}}$ in short-Weierstrass form defined over $GF(p)$, with as base point the point (GX, GY) , where parameters are as specified in Appendix M.3. This curve is denoted as Wei448.

M.2. Switching between Alternative Representations

Each affine point (u, v) of Curve448 corresponds to the point $(X, Y):=(u + A/3, v)$ of Wei448, while the point at infinity of Curve448 corresponds to the point at infinity of Wei448. (Here, we used the mappings of Appendix D.2 and that $B=1$.) Under this mapping, the base point (Gu, Gv) of Curve448 corresponds to the base point (GX, GY) of Wei448. The inverse mapping maps the affine point (X, Y) of Wei448 to $(u, v):=(X - A/3, Y)$ of Curve448, while mapping the point at infinity of Wei448 to the point at infinity of Curve448. Note that this mapping involves a simple shift of the first coordinate and can be implemented via integer-only arithmetic as a shift of $-(p-A)/3$ for the isomorphic mapping and a shift of $(p-A)/3$ for its inverse, where $\delta=(p-A)/3$ is the element of $GF(p)$ defined by

```
delta  24227957476520229684977460262933484478454712022910602009383006
      63935374427222435908954654612328921819766962948206145457870178326
      72736371
```

```
(=0x55555555 55555555 55555555 55555555 55555555 55555555
55555554 ffffffff ffffffff ffffffff ffffffff ffffffff ffffffff
ffff3473).
```

(Note that, depending on the implementation details of the field arithmetic, one may have to shift the result by $+p$ or $-p$ if this integer is not in the interval $[0,p-1]$.)

The curve Ed448 is isomorphic to the curve Curve448, where the base point (Gu, Gv) of Curve448 corresponds to the base point (Gx, Gy) of Ed448 and where the point at infinity and the point $(0,0)$ of order two of Curve448 correspond to, respectively, the point $(0, 1)$ and the point $(0, -1)$ of order two of Ed448 and where each other point (u, v) of Curve448 corresponds to the point $(c*u/v, (u+1)/(u-1))$ of Ed448, where c is the element of $GF(p)$ defined by

```
c  sqrt((A-2)/B)
```

```
19788846729546443953835400975385803825683515259105980214819977919
60874042320025157136042631277930307478554244641856917664538448351
92428
```

```
(=0x45b2c5f7 d649eed0 77ed1ae4 5f44d541 43e34f71 4b71aa96
c945af01 2d182975 0734cde9 faddbda4 c066f7ed 54419ca5 2c85de1e
8aae4e6c).
```

(Here, we used the mapping of Appendix D.1 and normalized this using the mapping of Appendix F.1 (where the element s of that appendix is set to c above).) The inverse mapping from Ed448 to Curve448 is defined by mapping the point $(0, 1)$ and the point $(0, -1)$ of order two of Ed448 to, respectively, the point at infinity and the point $(0,0)$ of order two of Curve448 and having each other point (x, y) of Ed448 correspond to the point $((y + 1)/(y - 1), c*(y + 1)/((y-1)*x))$ of Curve448.

The curve Ed448 is isomorphic to the Weierstrass curve Wei448, where the base point (Gx, Gy) of Ed448 corresponds to the base point (GX,GY) of Wei448 and where the identity element $(0,1)$ and the point $(0,-1)$ of order two of Ed448 correspond to, respectively, the point at infinity O and the point $(A/3, 0)$ of order two of Wei448 and where each other point (x, y) of Ed448 corresponds to the point $(X, Y):=((y+1)/(y-1)+A/3, c*(y+1)/((y-1)*x))$ of Wei448, where c was defined before. (Here, we used the mapping of Appendix D.3.) The inverse mapping from Wei448 to Ed448 is defined by mapping the point at infinity O and the point $(A/3, 0)$ of order two of Wei448 to, respectively, the identity element $(0,1)$ and the point $(0,-1)$ of order two of Ed448 and having each other point (X, Y) of Wei448 correspond to the point $(c*(X-A/3)/Y, (X-A/3+1)/(X-A/3-1))$ of Ed448.

Note that these mappings can be easily realized if points are represented in projective coordinates, using a few field multiplications only, thus allowing switching between alternative curve representations with negligible relative incremental cost.

M.3. Domain Parameters

The parameters of the Montgomery curve and the corresponding isomorphic curves in twisted Edwards curve and short-Weierstrass form are as indicated below. Here, the domain parameters of the Montgomery curve Curve448 and of the twisted Edwards curve Ed448 are as specified in [RFC7748]; the domain parameters of Wei448 are "new".

IMPORTANT NOTE: the supposed base point of Ed448 specified in [RFC7748] is incorrect, since it has order $2*n$, and $-$ in the notation below - that point is the point $(Gx,-Gy)=- (Gx, Gy)+(0,-1)$. The birational map in that document is also incorrect.

General parameters (for all curve models):

Appendix N. Further Cousins of Curve448

This section introduces some further curves related to Curve448 and explains their relationships.

N.1. Further Alternative Representations

The Weierstrass curve Wei448 is isomorphic to the Weierstrass curve Wei448.1 defined over $GF(p)$, with as base point the pair $(G1X, G1Y)$, and isogenous to the Weierstrass curve Wei448.-3 defined over $GF(p)$, with as base point the pair $(G3X, G3Y)$, where parameters are as specified in Appendix N.3 and where the related mappings are as specified in Appendix N.2.

The Edwards curve Ed448 is isogenous to the Edwards curve Edwards448 defined over $GF(p)$, with as base point the pair $(G1x, G1y)$, where parameters are as specified in Appendix N.3 and where the related mappings are as specified in Appendix N.2. For this curve, the domain parameter a is a square in $GF(p)$, whereas $d1$ is not, so the group laws of Appendix C.3 apply.

N.2. Further Switching

Each affine point (X, Y) of Wei448 corresponds to the point $(X', Y') := (X*s^2, Y*s^3)$ of Wei448.1, where s is the element of $GF(p)$ defined by

s 52322274343677442779379520589771028818568404587729117919590511061

 d2ca0171),

while the point at infinity of Wei448 corresponds to the point at infinity of Wei448.1. (Here, we used the mapping of Appendix F.3.) Under this mapping, the base point (GX, GY) of Wei448 corresponds to the base point $(G1X, G1Y)$ of Wei448.1. The inverse mapping maps the affine point (X', Y') of Wei448.1 to $(X, Y) := (X'/s^2, Y'/s^3)$ of

Wei448, while mapping the point at infinity O of Wei448.1 to the point at infinity O of Wei448. Note that this mapping (and its inverse) involves a modular multiplication of both coordinates with fixed constants s^2 and s^3 (respectively, $1/s^2$ and $1/s^3$), which can be precomputed.

The point at infinity and the point $(A/3,0)$ of order two of Wei448 both correspond to the point at infinity of Wei448.-3, while each other point (X,Y) of Wei448 corresponds to the point $(X',Y') := (X1*t^2, Y1*t^3)$ of Wei448.-3, where $(X1,Y1) = (u(X)/w(X), Y*v(X)/w(X)^2)$, where u , v , and w are the polynomials with coefficients in $GF(p)$ as defined in Appendix N.4.1 and where t is the element of $GF(p)$ defined by

```
t  23579450751475691430882365546539966269774125426758968522698856022

b6c7aaa5).
```

(Here, we used the isogenous mapping of Appendix F.4.) Under this isogenous mapping, the base point (GX,GY) of Wei448 corresponds to the base point $(G3X,G3Y)$ of Wei448.-3. The dual isogeny maps the point at infinity O and the point $(\tau,0)$ of order two of Wei448.-3, where τ is the element of $GF(p)$ defined by

```
tau 42178595713080601145580616893463205889346047807394283240821661315

```

to the point at infinity O of Wei448, while mapping each other point (X',Y') of Wei448.-3 to the affine point $(X,Y) := (u'(X1)/w'(X1), Y1*v'(X1)/w'(X1)^2)$ of Wei448, where $(X1,Y1) = (X'/t^2, Y'/t^3)$ and where u' , v' , and w' are the polynomials with coefficients in $GF(p)$ as defined in Appendix N.4.2. Under this dual isogenous mapping, the base point $(G3X, G3Y)$ of Wei448.-3 corresponds to a multiple of the base point (GX, GY) of Wei448, where this multiple is $l=2$ (the degree of the isogeny; see the description in Appendix F.4). Note that this isogenous map (and its dual) primarily involves the evaluation of three fixed polynomials involving the x -coordinate, which takes only a few modular

multiplications (less than 0.5% relative incremental cost compared to the cost of an elliptic curve scalar multiplication).

Each point (x_1, y_1) of Edwards448 with nonzero coordinates corresponds to the point (x, y) of Ed448, where

$$x = c*x_1*y_1/(1-d_1*x_1^2*y_1^2) = c*x_1*y_1/(2-x_1^2-y_1^2) \text{ and}$$

$$y = (1 + d_1*x_1^2*y_1^2)/(y_1^2-x_1^2) = -(x_1^2+y_1^2)/(x_1^2-y_1^2),$$

while each other point (i.e., a point of order 1, 2, or 4) corresponds to the identity element $(0,1)$ of Ed448. (Here, we used the 4-isogenous mapping of Appendix F.4). Under this isogenous mapping, the base point (G_1x, G_1y) of Edwards448 corresponds to the base point (G_x, G_y) of Ed448. The dual isogeny maps each point (x, y) of Ed448 to the point (x_1, y_1) of Edwards448, where

$$x_1 = (4*x*y/c)/(y^2-x^2) \text{ and}$$

$$y_1 = (1 - d*x^2*y^2)/(1 + d*x^2*y^2) = (2-x^2-y^2)/(x^2+y^2).$$

Under this dual isogenous mapping, the base point (G_x, G_y) of Ed448 corresponds to a multiple of the base point (G_1x, G_1y) of Edwards448, where this multiple is $l=4$ (the degree of the isogeny; see the description in Appendix F.4). Note that this isogenous map (and its dual) primarily involves the evaluation of three fixed polynomials, which takes only a few multiplications (less than 0.5% relative incremental cost compared to the cost of an elliptic curve scalar multiplication).

Each point (x_1, y_1) of Edwards448 with nonzero coordinates corresponds to the point (u, v) of Curve448, where

$$u = y_1^2/x_1^2 \text{ and } v = y_1*(2-x_1^2-y_1^2)/x_1^3,$$

while each other point (i.e., a point of order 1, 2, or 4) corresponds to the point at infinity of Curve448. Under this isogenous mapping, the base point (G_1x, G_1y) of Edwards448 corresponds to the base point (G_u, G_v) of Curve448. The dual isogeny maps both the point at infinity and the point $(0,0)$ of order two of Curve448 to the identity element $(0,1)$ of Edwards448, while each other point (u, v) of Curve448 corresponds to the point (x_1, y_1) of Edwards448, where

$$x_1 = 4*(u^2-1)*v/((u^2-1)^2+4*v^2) \text{ and}$$

$$y_1 = u*((u^2-1)^2-4*v^2)/(2*(u^2+1)*v^2-u*(u^2-1)^2).$$

Under this dual isogenous mapping, the base point (G_u, G_v) of Curve448 corresponds to a multiple of the base point (G_{1x}, G_{1y}) of Edwards448, where this multiple is $l=4$ (the degree of the isogeny; see above).

N.3. Further Domain Parameters

The parameters of the Weierstrass curve with $a=1$ that is isomorphic with Wei448 and the parameters of the Weierstrass curve with $a=-3$ that is isogenous with Wei448 are as indicated below. Both domain parameter sets can be exploited directly to derive more efficient point addition formulae, should an implementation facilitate this. The domain parameters of the Edwards curve Edwards448 are as specified in [RFC7748].

General parameters: same as for Wei448 (see Appendix M.3)

In the examples below, each curve point is represented using the compressed point representation (see Appendix I.8), but where (for historical reasons) the parity bit t of the compressed curve point in question is represented by 0x00 or 0x80 depending on whether $t=0$ or $t=1$, respectively. Notice that this representation corresponds to the compressed point representation of Appendix I.8, but with the bit-ordering in the 1-octet representation of t reversed. (Note that this puts the parity bit t in the leftmost bit position of the octet string if one follows the MSB/msb representation conventions.) For simplicity, this representation is again called the "squeezed" representation, although each point is now represented as a 57-octet string and, thereby, one octet longer than the tight representation of elements of $GF(p)$. As before, the ordering convention (see Appendix I.7) depends on the underlying curve model in question. Here, points of a Weierstrass curve are represented in tight MSB/msb-order, points of a Montgomery curve in tight LSB/msb-order, and points of a twisted Edwards curve in tight LSB/lbs-order. For points that are a public key, the corresponding private keys are represented as 56-octet strings, using the same ordering conventions as with the public keys. For affine points, we also give the tight representation of each of its coordinates (as 56-octet strings), using the same ordering conventions as used with the squeezed point representation. For further details, see the examples themselves.

As suggested in Appendix C.2, the v -coordinate of $k \cdot P_m$ can be indirectly computed from the u -coordinates of P_m , $k \cdot P_m$, and $(k+1) \cdot P_m$, and the v -coordinate of P_m , which allows computation of the entire point $k \cdot P_m$ (and not just its u -coordinate) if $k \cdot P_m$ is computed using the Montgomery ladder (as, e.g., [RFC7748] recommends), since that algorithm computes both u_1 and u_2 and the v -coordinate of the point P_m may be available from context.

The representation of k and the compressed representations of P_m and $k \cdot P_m$ in tight LSB/msb-order are given by

```
repr(k)      0x80aa5152 6526fe3a 841e4451 de85b629 8618c9d9 52630ac2
             2b107111 bd375d7c 9f191e4c 84b97208 c7232190 2d0562fe
             ca7a2de4 b9bbb3dc;

              8946709f bf9774e3 80,
```

where the leftmost bit of the rightmost octet indicates the parity of the v -coordinate of the point of Curve448 in question (which, in this case, are both one, since v and v_1 are odd). See Appendix H.2 and Appendix I for further detail on (squeezed) point compression.

The scalar representation and (squeezed) point representation illustrated above are consistent with the representations specified in [RFC7748], except that in [RFC7748] only an affine point's u -coordinate is represented (i.e., the v -coordinate of any point is always implicitly assumed to have an even value) and that the representation of the point at infinity is not specified. (Note that due to the bit-length of the prime p , the lossless representation requires an additional octet compared to the lossy representation without v -coordinate.) Another difference is that [RFC7748] allows non-unique representations of some elements of $GF(p)$, whereas our representation conventions do not (since tight).

A randomized representation (t_1 , t_2) of the point $k*P_m$ in tight LSB/msb order is given by

```
t1           642695971489808425948939115432957219707501931105169269237

dca7b0cd a80166fe 18c15250;

repr($k*P_w$) =0x80 8e1f426a 4a1af133 ff970fe2 76693c7a eaa78786
361b1cfe 4ccbd786 e020ba9a 0bf65ald 5d9a128a f85c63a2
79a00139 7aca56db 15341b9e,

where the leftmost bit of the leftmost octet indicates the parity of the Y-coordinate of the point of Wei448 in question (which, in this case, are both one, since Y and $Y1$ are odd). See Appendix H.1 and Appendix I for further detail on (squeezed) point compression.

The scalar representation is consistent with the representations specified in [SEC1]; the (squeezed) point representation illustrated above is "new". For completeness, we include a SEC1-consistent representation of the point P_w in affine format and in compressed format below.

The SEC1-compliant affine representation of the point P_w in tight MSB/msb-order is given by

aff(P_w) =0x6663c64e 5b9a1f6d cbee3f5f 839b7dd8 6f53cc3e 0a01dab3
e4a8314e 8d54be2a 4d63380b 692381bb ed7339fd dca7b0cd
a80166fe 18c15250

6bb38e82 8d52337f 6f0395ef dc16c776 52162f5e 309112ae
fc7401bf 0cfb0499 eb1ed555 bf507ebc c33b4753 2d6dc6c5
d68dealc cle4clfd,

whereas the SEC1-compliant compressed representation of the point P_w in tight MSB/msb-order is given by

```
compr(Pw)    =0x03 6663c64e 5b9a1f6d cbee3f5f 839b7dd8 6f53cc3e
              0a01dab3 e4a8314e 8d54be2a 4d63380b 692381bb ed7339fd
              dca7b0cd a80166fe 18c15250.
```

The SEC1-compliant uncompressed format $\text{aff}(P_w)$ of an affine point P_w corresponds to the right-concatenation of its X- and Y-coordinates, each in tight MSB/msb-order, prepended by the string 0x04, where the reverse procedure is uniquely defined, since elements of $\text{GF}(p)$ have a unique fixed-size representation. The (squeezed) compressed format $\text{repr}(P_w)$ corresponds to the SEC1-compliant compressed format by extracting the parity bit t from the leftmost bit of the leftmost octet of $\text{repr}(P_w)$, and replacing this leftmost octet with 0x02 or 0x03, depending on whether $t=0$ or $t=1$, respectively, where the reverse procedure is uniquely defined. For further details, see [SEC1]. Note that, due to the bit-length of the prime p , the squeezed compressed format $\text{repr}(P_w)$ and the SEC1-compliant compressed format $\text{compr}(P_w)$ have the same size.

A randomized representation (t_1, t_2) of the point $k \cdot P_w$ in tight MSB/msb order is given by

```
t1           655783099225353926682910498535559663266263823350679216116

where this uses the default completed mapping defined in Appendix K.6 and the mapping of Appendix K.4.3 (with the default square root function) and underlying 4-isogenous mapping between Edwards448 and Curve448 of Appendix N.2.

Appendix P. Random Integers in Z_n

Any probability distribution on the interval $[0, N-1]$ can be converted to a probability distribution on $[0, n-1]$, via a suitable function that maps inputs from the source distribution $[0, N-1]$ to values in the interval $[0, n-1]$. We consider three such functions, each with the property that if the source distribution on $[0, N-1]$ is statistically close to the uniform distribution, then so is the output distribution on $[0, n-1]$. (Here, we assume n and N to be integers of cryptographic interest, so large.) In practical applications, one can use these functions to convert the output of a cryptographically strong random bit generator (where N is a power of two and after conversion of the random bit string to an integer via the BS2I mapping of Appendix I.2) to a pseudo-random integer in the interval $[0, n-1]$, where the bias is small if N is suitably picked.

We consider mappings that convert an output of the source distribution to an integer in the interval $[0, n-1]$ via modular reduction (Appendix P.1), via scaling (Appendix P.2), or via a membership test (Appendix P.3). For suitably picked N values and not too poor source distributions, the first two mappings never fail and any bias introduced by the conversion process can be made negligible in practice, while the third mapping (if it does not fail) inflates the bias by a small factor only in practice. (For details, see the remarks following each of the mappings below.)

NOTE: 1 Each of the mappings below may yield a zero output value. One can modify each such mapping to always yield nonzero outputs, by setting output x to 1 if the original mapping would yield $x=0$ for a specific input y and leaving the mapping the same otherwise (henceforth called the modified conversion function). This modification has negligible impact on the bias and does yield a conversion function to integers in the interval $[1, n-1]$. A similar remark applies if $n=h*n_1$, where h is a small integer: in that case, one can locally modify each mapping to always yield outputs in the interval $[0, h*n_1-1]$ that are not divisible by n_1 , simply by setting output x to $x+1$ if the original mapping would otherwise yield $x=0 \pmod{n_1}$. (Notice that both modifications coincide if $h=1$.) These modifications may be useful if one wishes to generate integers in an interval of size n and where one wishes to avoid specific output values (e.g., if one wishes to generate high-order points of a curve of order $h*n_1$, with co-factor h (see Appendix B.1)). For simplicity, we again refer to this as "the" modified conversion function (or h -modified conversion function, if h is not clear from context).

P.1. Conversion to Integers in Z_n via Modular Reduction

This function maps each integer y in the interval $[0, N-1]$ to its remainder modulo n , i.e., y is mapped to $x := y \pmod{n}$.

One can show that the bias introduced by this conversion function is at most $\epsilon := 2 \cdot \rho \cdot (1 - \rho) / (N/n)$, where $r := N \pmod{n}$ and where $\rho := r/n$. Details are out of scope.

Note that if n does not divide N , this invariably introduces some bias, no matter the quality of the source distribution. In particular, the statistical distance of the distribution on Z_n can be much larger than the statistical distance of the source distribution on Z_N , since the bias introduced by the modular reduction step may be significantly larger than the bias of the source distribution on Z_N if the value ρ above is not close to zero or one and if n/N is not sufficiently small. The maximum bias is, however, easy to determine from n and N . In particular, if the bit-length of N is sufficiently larger than that of n , the bias introduced by the modular reduction operation is negligible in practice. The same holds if N is close to a multiple of n (e.g., if n is close to a power of two and the input distribution is generated by a high-quality random bit generator with outputs of fixed bit-length).

Note: In practice, one does not determine the maximum bias ϵ from n and N , but rather specifies a required upper bound (usually set to a value at most 2^{-64}) for ϵ and subsequently determines the minimal value of N for which this upper bound indeed applies, as a function of n . Table 3 illustrates this for several curves of practical interest.

Table 3: Minimum bit-length of N for which the bias (epsilon) introduced by converting integers in Z_N to integers in Z_n via modular reduction or via scaling is lower than the indicated eps0 value, for some curves of practical interest (where n is the order of the base point of the curve in question)

P.2. Conversion to Integers in Z_n via Scaling

This function maps each integer y in the interval $[0, N-1]$ to the integer $x := \text{floor}(n*y/N)$, where the floor function rounds real numbers downwards to an integer (i.e., $\text{floor}(z)$ is the unique integer i for which z is an element of the interval $[i, i+1)$ of real numbers).

One can show that the bias introduced by this conversion function is at most $\text{epsilon} := 2*\rho*(1-\rho)/(N/n)$, where $r := N \pmod n$ and where $\rho := r/n$. Details are out of scope.

The same remarks as in Appendix P.1 apply.

Note: this mapping corresponds to interpolation on the line with endpoints $(0,0)$ and (N,n) , where values are truncated to integers. The division operation in this conversion function reduces to a binary string truncation operation if N is a power of two (which is often the case in practice). See also [comm-FIPS-186-5], pp. 80-82.

P.3. Conversion to Integers in Z_n via the Discard Method

This function (defined for N at least n) is the identity map on the interval $[0, n-1]$ and fails for each integer y outside this interval.

One can show that the statistical distance of the distribution on Z_n is at most roughly N/n times as large as the statistical distance of the source distribution on Z_N (if the latter is relatively negligible compared to n/N). Details are out of scope.

Note that, under the above conditions, if $N=2^m$ and if n has bit-length m , this conversion function fails with probability $1 - n/N$ (which is at most $1/2$) and, if it succeeds, does not inflate the statistical distance by more than (roughly) a factor two.
